PUBLISHER'S PREFACE

In making plans for new editions of our handbooks in mechanical engineering and in electrical engineering, it soon became clear that engineering science and practice had developed to such an extent that handbooks were growing beyond all practical bounds. They had become both bulky and inconvenient and contained much duplicated material. In order to solve the problems presented by these conditions, the editors of our various handbooks were asked to serve as an advisory editorial board.

This board recommended, first, that the fundamental material underlying all engineering be published in a separate volume, and, second, that the existing handbooks as they are revised be issued in several volumes containing material closely related to the specialized branches of engineering. As a result of these recommendations, the Wiley Engineering Handbook Series has been initiated, which in the beginning will comprise the following: Eshbach's "Handbook of Engineering Fundamentals"; Kent's "Mechanical Engineers' Handbook" in two volumes, viz., "Power" and "Design and Shop Practice"; Pender's "Electrical Engineers' Handbook" in two volumes, viz., "Electric Power" and "Communication and Electronics."

This division has also made it possible to devote more space to the various topics so that the entire new series of handbooks contains more complete information on all topics than heretofore has been possible. It is our hope that this new plan will give engineers information that is more useful, more complete, and in more convenient form.

JOHN WILEY & SONS, INC.

EDITOR'S PREFACE

This handbook has been prepared for the purpose of embodying in a single volume those fundamental laws and theories of science which are basic to engineering practice. It is essentially a summary of the principles of mathematics, physics, and chemistry, the properties and uses of engineering materials, the mechanics of solids and fluids, and the commonly used mathematical and physical tables, to which has been added a discussion of contractual relations. Thus, with the exception of the technics of surveying and drawing, there is included the fundamental technology common to nearly all engineering curricula.

It is hoped, that, as a unit in itself, it will be valuable to both student and practicing engineer and, as a companion to any other volume of the Wiley Handbook Series, will give a degree of completeness in scope not previously attainable in this form.

Although each of the contributors as a matter of course checked the technical accuracy of his material, every section has been read by at least two other competent engineers as an additional precaution. The more important tables were checked against at least two independent sources by different individuals.

Appreciation is expressed to all who have cooperated in giving advice and assistance. Among them the editor feels particularly indebted to Mr. H. C. Jennison, Technical Manager, and Mr. W. R. Hibbard, Assistant Metallurgist, of the American Brass Company, who completed the manuscript begun by Mr. W. H. Bassett, deceased; Dr. Lyman J. Briggs, Director of the National Bureau of Standards, Dr. J. W. Finch, Director of the Bureau of Mines, and members of their staffs who reviewed portions of the manuscript and made valuable suggestions; and to editors of other Wiley Handbooks, national societies, corporations, and others for permission to use material previously published by them.

Ovid W. Eshbach

LIST OF CONTRIBUTORS

John L. Barnes, S.M., A.M., Ph.D., Department of Mathematics, Tufts College.—*Mathematical and Physical Tables,* and *Mathematics.*

The late W. H. Bassett, The American Brass Co., Waterbury, Conn.—*Copper and Wrought Copper-base Alloys.*

Christopher H. Bierbaum, B.S., M.E., Vice President and Consulting Engineer, Lumen Bearing Co., Buffalo, N. Y.—*Bearing Metals.*

J. G. Brainerd, D.Sc. in E.E., Asst. Prof. Moore School of Elec. Eng., University of Pennsylvania.—*Tables of Conversion Factors—Units of Weights and Measures, Gages,* and *Alignment Charts—Nomograms.*

Carl C. Chambers, D.Sc. in E.E., Moore School of Elec. Eng., University of Pennsylvania.—*Conduction of Electricity in Solids and Fluids.*

W. M. Corse, Metallurgical and Chemical Engineer, Washington, D. C.—*Sand-cast Copper-base Alloys.*

Theodore Crane, C.E., M.A., Professor of Architectural Engineering, School of Fine Arts, Yale University.—*Reinforced Concrete,* and *Cement, Concrete, Lime, Mortar and Plaster.*

Jasper O. Draffin, M.S., Professor of Theoretical and Applied Mechanics, Materials Testing Laboratory, University of Illinois.—*Mechanics of Materials, Testing of Materials,* and *Stone, Brick, and Terra-cotta.*

H. L. Dryden, Ph.D., Chief of the Division of Mechanics and Sound, National Bureau of Standards.—*Wind Pressure on Structures.*

Junius D. Edwards, Asst. Director of Research, Aluminum Research Laboratories, Aluminum Co. of America, New Kensington, Pa.—*Aluminum and Aluminum Alloys.*

Churchill Eisenhart, B.A., M.A., Student at Institute of Applied Statistics, University of London.—*Precision of Measurements.*

Ovid W. Eshbach, E.E., M.S., Personnel Department, Am. Tel. and Tel. Co., New York, N. Y.—*Mathematical and Physical Tables.*

Maurice J. Fish, Ph.D., Instructor in Mathematics, Buffalo Collegiate Center, Buffalo, N. Y.—*Trigonometry, Analytic Geometry, Calculus, Differential Equations, Functions of Complex Variables,* and *Vector Analysis.*

J. C. Fox, B.S. in Chem., Chief Chemist and Metallurgist, Doehler Die Casting Co., Toledo, O.—*Die-Casting Alloys.*

John A. Gann, Ph.D., Chief Metallurgist, The Dow Chemical Co., Midland, Mich.—*Magnesium and Magnesium Alloys.*

E. B. Guenther, M.E., Technical Department, Harbison-Walker Refractories Co., Pittsburgh, Pa.—*Refractories.*

Paul E. Hemke, M.A., Ph.D., Head of the Department of Aeronautical Engineering, Rensselaer Polytechnic Institute.—*Mechanics of Fluids.*

Zay Jeffries, Metallurgical Engineer, Nela Park, Cleveland, O.—*Aluminum and Aluminum Alloys, Tungsten,* and *Molybdenum.*

Robert Thurston Kent, M.E., Consulting Engineer, Verona, N. J.—*Mathematical Tables.*

Paul J. Kiefer, A.B., M.E., Professor of Mechanical Engineering, U. S. Naval Postgraduate School.—*Engineering Thermodynamics.*

Henry C. Knutson, E.E., M.E.E., Asst. Prof., Department of Elec. Eng., Lehigh University.—*Tables on Physical Properties of Materials, Symbols and Abbreviations, Electrical Conductor Materials,* and *Timber.*

R. B. Lindsay, Ph. D., Professor of Theoretical Physics and Chairman of the Department of Physics, Brown University.—*Acoustics.*

Robert J. Martin, B.S., M.A., Ass't Meteorologist, U. S. Weather Bureau, Washington, D. C.—*Meteorology.*

Joseph Mattiello, Ph.D., Technical Director of the Hilo Varnish Corp., Brooklyn, N. Y.—*Chemistry,* and *Paints, Enamels, Varnishes, and Lacquers.*

J. Spotts McDowell, B.S., Research Engineer, Harbison-Walker Refractories Co., Pittsburgh, Pa.—*Refractories.*

D. F. Miner, Manager, Material and Process Engineering Dept., Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.—*Welding, Brazing and Soldering Materials, Electrical Conductor Materials, Electric Insulating Materials, Adhesive Materials,* and *Lubricants.*

H. F. Moore, M.E., M.M.E., D.Sc., Research Professor of Engineering Materials, University of Illinois.—*Timber.*

W. M. Peirce, B.S. in Ch.E., M.S., Chief, Metal Research Division, The New Jersey Zinc Co., Palmerton, Pa.—*Zinc and Zinc-base Alloys.*

Janvier M. Rice, E.E., Executive Engineer, Curtiss Aeroplane & Motor Co., Inc., Buffalo, N. Y.—*Arithmetic, Algebra, Geometry,* and *Theoretical Mechanics.*

R. L. Sackett, C.E., Dean of the School of Engineering, Director of the Engineering Experiment Station and of Engineering Extension, Pennsylvania State College.—*Contracts.*

J. B. Seastone, Engineer, Metals Section, Material & Process Engineering Dept., Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.—*Magnetic Materials.*

Frank N. Speller, B.A.Sc., D.Sc., Director, Dept. of Metallurgy and Research, National Tube Co. (Subsidiary U. S. Steel Corp.), Pittsburgh, Pa.—*Corrosion of Metals.*

Bradley Stoughton, Ph.B., B.S., Dean of Engineering, Head of Dept. of Metallurgy, Lehigh University.—*General Properties of Metals and Alloys, Iron and Steel,* and *Metal Joining.*

Milton C. Stuart, M.E., Professor of Experimental Mechanical Engineering, Lehigh University.—*Engineering Thermodynamics.*

Irven A. Travis, M.Sc. in E.E., Moore School of Electrical Engineering, University of Pennsylvania.—*Electricity and Magnetism.*

S. B. Tuwiner, B.S., Ch.E., Ph.D., Research Engineer, Phelps Dodge Corp., New York, N. Y.—*Chemistry.*

Ernst Weber, Dr. Phil., Dr. Techn. Ing., Research Professor of Elec. Engr., Polytechnic Institute of Brooklyn.—*Physical Units and Standards,* and *Radiation and Light.*

Charles Weyl, M.Sc. in E.E., Asst. Prof., Moore School of Elec. Eng., University of Pennsylvania.—*Electricity and Magnetism.*

Edgar W. Woolard, Meteorologist, U. S. Weather Bureau, Washington, D. C.—*Meteorology.*

Robert Worthington, 20 Exchange Place, New York, N. Y.—*Nickel and Non-ferrous Nickel Alloys.*

GENERAL TABLE OF CONTENTS

Detailed tables of contents are given at the beginning of each section. An alphabetical index appears following Section 13.

SECTION 1. MATHEMATICAL AND PHYSICAL TABLES

PAGE
Symbols and Abbreviations.......... 1- 02
Mathematical Tables................ 1- 11
Physical Properties of Materials...... 1-121
Tables of Conversion Factors—Units of Weights and Measures............ 1-130
Gages............................ 1-149
Standard Structural Sizes............ 1-153

SECTION 2. MATHEMATICS

Arithmetic........................ 2- 02
Algebra.......................... 2- 06
Mathematics of Finance............ 2- 22
Geometry......................... 2- 32
Trigonometry..................... 2- 53
Plane Analytic Geometry........... 2- 61
Solid Analytic Geometry............ 2- 70
Differential Calculus............... 2- 75
Integral Calculus.................. 2- 86
Differential Equations.............. 2- 99
Solution of Linear Constant-coefficient Integro-differential Equations by the Laplacian Transformation (Operational Calculus).................. 2-108
Functions of Complex Variables...... 2-111
Vector Analysis.................... 2-112
Alignment Charts (Nomograms)...... 2-116
Precision of Measurements.......... 2-123

SECTION 3. PHYSICAL UNITS AND STANDARDS

Dimension Systems................ 3- 02
Unit Systems...................... 3- 12
Units and Standards................ 3- 21
Dimensional Analysis............... 3- 36

SECTION 4. THEORETICAL MECHANICS

Statics........................... 4- 02
Kinematics........................ 4- 27
Kinetics.......................... 4- 34

SECTION 5. MECHANICS OF MATERIALS

Simple Stresses.................... 5- 02
Beams............................ 5- 19
Columns.......................... 5- 36
Shafts............................ 5- 48
Cylinders, Plates, Rollers, and Riveted Joints.......................... 5- 52
Reinforced Concrete................ 5- 59
Testing of Materials................ 5- 81

SECTION 6. MECHANICS OF FLUIDS

Properties of Fluids, Divisions of Fluid Mechanics........................ 6- 02
Fluid Statics...................... 6- 11
Fluid Dynamics.................... 6- 15

SECTION 7. ENGINEERING THERMODYNAMICS

Principles of Thermodynamics........ 7- 02
Gases............................ 7- 15
Liquids and Vapors................. 7- 31
The Steam Power Plant............. 7- 52
The Internal-combustion Engine...... 7- 71
PAGE
Refrigeration...................... 7- 77
Gas and Vapor Mixtures, Humidity, and Air Conditioning............. 7- 85

SECTION 8. ELECTRICITY AND MAGNETISM

Electron Theory................... 8- 02
Direct-current Circuits............. 8- 09
Electrokinetics and the Magnetic Circuit........................ 8- 18
Electrostatics and the Dielectric Circuit 8- 35
Alternating-current Circuits.......... 8- 45
Transients........................ 8- 57
Conduction of Electricity in Solids and Fluids.......................... 8- 62

SECTION 9. RADIATION AND LIGHT, ACOUSTICS, AND METEOROLOGY

Theory of Radiation................ 9- 02
Geometry of Radiation............. 9- 09
Physics of Radiation............... 9- 15
Physiology of Radiation............ 9- 26
Acoustics........................ 9- 35
Meteorology 9- 55

SECTION 10. CHEMISTRY

General Chemistry................. 10- 02
Industrial Chemistry............... 10- 12
Qualitative Analysis................ 10- 31
Electrochemistry................... 10- 36

SECTION 11. METALLIC MATERIALS

General Properties of Metals and Alloys 11- 02
Corrosion of Metals................ 11- 05
Iron and Steel..................... 11- 12
Copper and Copper-base Alloys....... 11- 39
Zinc and Zinc-base Alloys............ 11- 52
Aluminum and Aluminum Alloys..... 11- 58
Nickel and Non-ferrous Nickel Alloys.. 11- 70
Magnesium and Magnesium Alloys.... 11- 75
Tungsten........................ 11- 79
Molybdenum..................... 11- 81
Die-casting Alloys.................. 11- 82
Bearing Metals.................... 11- 84
Welding, Brazing, and Soldering Materials....................... 11- 89
Electrical Conductor Materials....... 11- 92
Magnetic Materials................. 11-101
Miscellaneous Materials............. 11-109

SECTION 12. NON-METALLIC MATERIALS

Cement, Concrete, Lime, Mortar, and Plaster......................... 12- 02
Stone, Brick, and Terra-cotta......... 12- 14
Refractories....................... 12- 20
Thermal Insulating Materials......... 12- 32
Timber........................... 12- 38
Paints, Enamels, Varnishes, and Lacquers........................ 12- 50
Electric Insulating Materials......... 12- 58
Lubricants........................ 12- 75
Fuels and Explosives................ 12- 77
Adhesive Materials.................. 12- 80
Miscellaneous Materials............. 12- 82

SECTION 13. CONTRACTS

Contracts......................... 13- 02

For contents of other handbooks of this series, see pages following Index of this volume.

This book is divided into sections, each section carrying its independent sequence of page numbers. For example, 3-15 indicates Section 3, page 15.

Table 2. Symbols for Mathematical Operations

References: American Standard for Mathematical Symbols (AESC Report Z10f). Mathematical Association of America (National Committee Report, 1923, Chapter 8).

Addition and Subtraction

$a + b$, a plus b
$a - b$, a minus b
$a \pm b$, a plus or minus b
$a \mp b$, a minus or plus b

Multiplication and Division

$a \times b$, or $a \cdot b$, or ab, a times b
$a \div b$, or $\frac{a}{b}$, or a/b, a divided by b

Symbols of Aggregation

() parentheses
[] brackets
{} braces
$\overline{}$ vinculum

Equalities and Inequalities

$a = b$, a equals b
$a \approx b$, a approximately equals b
$a \neq b$, a is not equal to b
$a > b$, a is greater than b
$a < b$, a is less than b
$a \geqq b$, a equals or is greater than b
$a \leqq b$, a is less than or equals b
$a \equiv b$, a is identical to b
$a \longrightarrow b$, or $a \doteq b$, a approaches b as a limit

Proportion

$a/b = c/d$, or $a : b :: c : d$, a is to b as c is to d
$a \propto b$, a varies directly as b
%, per cent

Powers and Roots

a^2, a squared
a^n, a raised to the nth power
$\sqrt[3]{a}$, cube root of a
$\sqrt[n]{a}$, or $a^{1/n}$, nth root of a
a^{-n}, $1/a^n$
$3.14 \times 10^4 = 31{,}400$
$3.14 \times 10^{-4} = 0.000314$

Miscellaneous

$a! = 1 \cdot 2 \cdot 3 \ldots a$, factorial a
$P(n, r) = n(n-1)(n-2)\ldots(n-r+1)$
$C(n, r) = \frac{P(n, r)}{r!} = \binom{n}{r}$ = binomial coefficients
$|a|$ = absolute value of a
i (or j) $= \sqrt{-1}$, imaginary unit
$\pi = 3.1416$, ratio of the circumference to the diameter of a circle
∞, infinity

Plane Geometry

$\angle$, angle
$\triangle$, triangle
$\parallel$, parallel
$\perp$, perpendicular
$\odot$, circle
▱, parallelogram
$\therefore$, therefore
° ′ ″, degree, minute, second
′ ″, feet, inches

Logarithms

$\log a = \log_{10} a$, common logarithm of a or log of a to the base 10
$\ln a = \log_e a$, natural logarithm of a or log of a to the base e ($e = 2.718$)
$\log^{-1} a$, number whose log is a

Trigonometry

sin, cos, tan
cosec or csc, sec, cot or ctn } trigonometric functions
vers, covers
$\sin^{-1}$, $\cos^{-1}$, etc., inverse of the functions

Analytic Geometry

x, y, z; ξ, η, ζ, rectangular coordinates
ρ, s, intrinsic coordinates
ρ, radius of curvature
s, length of arc
r, θ, polar coordinates
ψ, angle from radius vector to tangent
r, θ, ϕ, spherical coordinates
θ, co-latitude
ϕ, longitude
r, θ, z, cylindrical coordinates
e, eccentricity in conics
p, semi latus rectum in conics
$l = \cos\alpha$, $m = \cos\beta$, $n = \cos\gamma$, direction cosines

Calculus

$y = f(x)$, y is a function of x
$y' = f'(x) = \frac{dy}{dx} = D_x y$, derivative of $y = f(x)$ with respect to x
$y'' = f''(x) = \frac{d(y')}{dx} = D^2{}_x y = \frac{d^2y}{dx^2}$, second derivative of $y = f(x)$ with respect to x
$u = f(x, y)$, u is a function of x and y
$u_x = f_x(x, y) = D_x(u) = \frac{\partial u}{\partial x}$, partial derivative of $u = f(x, y)$ with respect to x
$u_{xy} = f_{xy}(x, y) = D_y(D_x u) = \frac{\partial^2 u}{\partial y \partial x}$, second partial derivative of $u = f(x, y)$ with respect to x and y
Δy, increment of y
dy, differential of y
δy, variation of y
$\sum\limits_{i=a}^{b}$, summation over i from a to b
$\lim\limits_{x \to a} (y) = b$, $y \to b$ as $x \to a$
$\int$, integral of
$\int_a^b$, definite integral of

Vector Analysis

$\mathbf{i}, \mathbf{j}, \mathbf{k}$, unit vectors along the axes (right-handed system)
$\mathbf{a} \cdot \mathbf{b} = (\mathbf{ab}) = S\mathbf{ab}$, scalar product of $\mathbf{a}$ and $\mathbf{b}$
$\mathbf{a} \times \mathbf{b} = [\mathbf{ab}] = V\mathbf{ab}$, vector product of $\mathbf{a}$ and $\mathbf{b}$
Vectors are indicated in print by **bold-faced type.**

Table 3. Abbreviations for Engineering Terms

Note: This list is a selection of American Tentative Standard abbreviations, for scientific and engineering terms, recommended by the American Standards Association. (See ASA, Z10i—1932.)

Absolute	abs
Acre	acre

Millihenry	mh
Milliliter	ml
Millimeter	mm
Millimicron	mμ or m mu
Million	spell out
Millivolt	mv
Minimum	min
Minute	min
Minute (angular measure)	′
Ohm	spell out
Ounce	oz
Ounce-foot	oz-ft
Ounce-inch	oz-in.
Peck	pk
Pint	pt

Table 3. Abbreviations for Engineering Terms—*Continued*

Term	Abbreviation	Term	Abbreviation
Potential	spell out	Spherical candle power	scp
Pound	lb	Square	sq
Pound-foot	lb-ft	Square centimeter	sq cm or cm^2
Pound-inch	lb-in.	Square foot	sq ft
Pounds per square foot	lb per sq ft	Square inch	sq in.
Pounds per square inch	lb per sq in.	Square kilometer	sq km or km^2
Power factor	spell out	Square meter	sq m or m^2
Quart	qt	Square root of mean square	rms
Radian	spell out	Standard	std
Reactive kilovolt-ampere	rkva	Tangent	tan
Reactive volt-ampere	rva	Temperature	temp
Revolutions per minute	rpm	Thousand	M
Revolutions per second	rps	Ton	spell out
Rod	spell out	Versed sine	vers
Root mean square	rms	Volt	v
Secant	sec	Volt-ampere	va
Second	sec	Watt	w
Second (angular measure)	"	Watthour	whr
Sine	sin	Weight	wt
Specific gravity	sp gr	Yard	yd
Specific heat	sp ht	Year	yr

Table 4. Symbols for Physical Quantities

NOTE: The most frequently used American Standard and Tentative Standard Symbols are included in this table. Reference to the sources, or publications of the American Standards Association, are indicated by the numbers, in parentheses, which follow the names of the quantities. These numbers correspond to the following:

(1) American Tentative Standard Aeronautical Symbols, ASA, Z10e–1929.
(2) American Institute of Electrical Engineers Standards ASA, Z10g1—1929.
(3) American Tentative Standard Symbols for Heat and Thermodynamics ASA, Z10c—1931.
(4) American Tentative Standard Symbols for Hydraulics ASA, Z10b—1929.
(5) American Standard Symbols for Mechanics, Structural Engineering and Testing Materials, ASA, Z10a—1932.
(6) American Standard Symbols for Photometry and Illumination ASA, Z10d—1930.

Where possible, capital letters denote total quantities and small letters denote specific quantities, or quantities per unit.

NAME OF QUANTITY	SYMBOL
Absorption factor (6)	α
Acceleration, angular (5)	α
Acceleration, linear, general (4) (5)	a
Acceleration due to gravity, general (1) (3) (4) (5)	g
International Adopted Standard (3)	g_o
local (3)	g_L
Adiabatic factor (3)	Y
Admittance (2)	Y, y
Air speed (1)	V
indicated (1)	V_i
Altitude (1)	h
Angle	
of attack (1)	α
between the absolute velocity of the water and the velocity of the runner at any point, measured in degrees (4)	α
between the relative velocity of the water and the velocity of the runner at any point, measured in degrees (4)	β
dihedral (1)	γ
of downwash (1)	ϵ
effective helix (1)	Φ
of pitch (1)	θ
of roll or bank (1)	ϕ
of set of control surface * (1)	δ
of stabilizer setting with reference to lower wing (1)	β
of wing setting (angle between the wing chord and the thrust line) (1)	i_w
of yaw (1)	ψ
Angular	
acceleration (5)	α
displacements	
in roll (1)	ϕ
in pitch (1)	θ
in yaw (1)	ψ
distance (5)	θ
frequency (2)	ω
velocity (1) (2) (3) (4) (5)	ω

Table 4. Symbols for Physical Quantities—*Continued*

NAME OF QUANTITY	SYMBOL
Area (3) (4) (5)	A
Area * (1)	S
Area ratio (1)	$\frac{S}{b^2} = \lambda$
Aspect ratio (1)	$\frac{b^2}{S}$
Attack, angle of (1)	α
Axes	
of aircraft (left-handed)	
longitudinal (1)	X
lateral (1)	Y
normal (1)	Z
through any point (5)	$X–X$, $Y–Y$, $Z–Z$
Axial breadth or depth of runner entrance (4)	B
Axis, neutral; distance to extreme fiber (5)	c
Bazin's coefficient of roughness (4)	m
Bending moment (5)	M
Breadth (5)	b
Brightness (6)	B
Candlepower (6)	I
mean horizontal (6)	I_h
mean lower hemispherical (6)	I_l
mean spherical (6)	I_s
mean upper hemispherical (6)	I_u
mean zonal (6)	I_z
Capacitance, capacity (2)	C
Ceiling (1)	H
Center of gravity (1)	c.g.
coefficient (with respect to mean chord) (1)	C_g
Center of pressure (1)	c.p.
coefficient of (1)	C_p
Center of rotation (5)	O
Chezy's coefficient (4)	C
Chord length (1)	c
Climb, rate of (1)	r
Coefficient, absolute (1)	C
Concentrated load (5)	F
Concentration (3)	C
Conductance	
electrical (2)	G, g
thermal (3)	C
thermal, per unit area (3)	C_A
Conductivity	
electrical (2)	γ
thermal (3)	k
Constants (5)	C
Contraction, coefficient of (4)	c_c
Current † (2)	I, i
Curvature, radius of (5)	ρ
Damping coefficient (1)	λ
Deflection (5)	y
of a panel point of a truss (5)	Δ
Density (3) (5)	ρ, d
Density (1) (4)	ρ
relative to standard air density (1)	σ
Depth (5)	d
Depth of flow, channels (4)	d
Diameter (1) (3) (4) (5)	D
of runner or impeller (4)	D
of runner or impeller vanes at the middle of entrance space (4)	D_1
of runner or impeller throat (inside diameter of band or shroud ring) (4)	D_{th}
Dielectric	
constant (2)	K or ϵ
flux (2)	Ψ
flux density (2)	D
Difference of potential †‡ (2)	E, e
Dihedral angle (1)	γ
Discharge	
coefficient of (4)	c_d
rate of; or flow (4)	Q
Displacement, phase (2)	θ or ϕ

Table 4. Symbols for Physical Quantities—*Continued*

NAME OF QUANTITY	SYMBOL
Displacements	
angular	
in roll (1)	ϕ
in pitch (1)	θ
in yaw (1)	ψ
longitudinal (1)	x
lateral (1)	y
normal (1)	z
Distance	
angular (5)	θ
linear (5)	s
from center of gravity to center of pressure of horizontal tail surface (1)	f
Downwash, angle of (1)	ϵ
Drag	
absolute coefficient of (1)	C_D
coefficient of induced (1)	C_{Di}
coefficient of parasite (1)	C_{Dp}
coefficient of profile (1)	C_{Do}
induced (1)	D_i
parasite (1)	D_p
profile (1)	D_o
Dynamic (or impact) pressure (1)	q
Eccentricity of application of load (5)	e
Efficiency (1) (2) (3)	η
Efficiency (3) (4)	e
hydraulic (4) (5)	e_h
mechanical (4) (5)	e_m
volumetric (5)	e_v
Elasticity	
bulk modulus, of water (4)	K
modulus of (5)	E
Electric potential †‡ (2)	E, e
Electricity, quantity of (2)	Q, q
Electromotive force † (2)	E, e
Electrostatic	
flux (2)	Ψ
flux density (2)	D
Elongation, unit (5)	δ
Energy (2)	W
internal; intrinsic § (3)	U, u
per unit time (power) (4)	P
Enthalpy § (3)	H or h
of dry saturated vapor (3)	h_g
of saturated liquid (3)	h_f
Entropy § (3)	S, s
Expansion, exponent of polytropic (3)	n
Flux	
density	
dielectric; electrostatic (2)	D
magnetic (2)	B
dielectric (2)	Ψ
luminous (6)	F
radiant (6)	Φ
Force (4) (5)	F
in any bar of a framed structure due to a load of unity applied at any point in any direction (5)	u
cross wind (1)	C
cross wind, absolute coefficient (1)	C_c
electromotive † (2)	E, e
magnetomotive (2)	$\mathfrak{F}$
moment of (5)	M
resultant (1)	R
total load (3)	F
Forces (parallel to axes)	
longitudinal (1)	X
lateral (1)	Y
normal (1)	Z
Frequency, angular (2)	ω
Frequency (2)	f
Frequency (harmonic motion) (5)	f or n

Table 4. Symbols for Physical Quantities—*Continued*

Name of Quantity	Symbol
Friction	
coefficient of sliding (5)	f
factor used in expressing pipe-loss (4)	f
Gap (1)	G
Gas constant (3)	R
Gibbs' function, total potential function (3)	z or ζ
Gyration, radius of (5)	k
Head, at any point (4) (5)	H or $\mathbf{h}$
elevation (4)	z
lost * (4)	h
potential (4)	z
pressure (4)	h_p
velocity (4)	h_v
velocity, of approach, weirs (4)	h_0
Heat	
content; enthalpy § (3)	H, h
content of dry saturated vapor; enthalpy of dry saturated vapor (3)	h_g
content of saturated liquid; enthalpy of saturated liquid (3)	h_f
equivalent of work (3)	$\frac{1}{J}$ or A
mechanical equivalent of (3)	J
specific, at constant pressure (3)	c_p
specific, at constant volume (3)	c_v
ratio of specific (3)	κ or k
transfer, overall coefficient of (3)	U
transfer, surface coefficient of (3)	h
of vaporization at constant pressure (3)	L or h_{fg}
Height (5)	h
crest, weirs (4)	Z
Helix, effective angle (1)	Φ
Helmholtz' free energy; internal potential function (3)	ψ
Hydraulic radius (4)	R
Hydraulic slope (4)	S
Illumination (6)	E
Impedance (2)	Z, z
Indraft (inflow velocity) (1)	V'
Inductance (2)	L
mutual (2)	M
self (2)	L
Inertia, moment of	
polar (5)	J
rectangular (5)	I
Joule-Thomson's coefficient (3)	μ
Kutter's coefficient of roughness (4)	n
Length (3) (4) (5)	L
crest, weirs (4)	B
Lift (1)	L
absolute coefficient of (1)	C_L
drag ratio (1)	$\frac{L}{D}$
Light, quantity of (6)	Q
Load	
concentrated (5)	F
eccentricity of application of (5)	e
factor (1)	n
per unit distance (5)	w
total (5)	W
Loading	
specific * (1)	w
power; weight per unit power (1)	w_p
wing; weight per unit area (1)	w_s
Luminous	
flux (6)	F
intensity (candlepower) (6)	I
Magnetic	
intensity (2)	H
flux (2)	Φ
density (2)	B
Magnetomotive force (2)	$\mathfrak{F}$
Mass (3) (5)	m

Table 4. Symbols for Physical Quantities—*Continued*

NAME OF QUANTITY	SYMBOL
Mechanical equivalent of heat (3)	J
Modulus	
of elasticity (5)	E
bulk, of elasticity of water (4)	K
ratio between, of elasticity of steel and modulus of elasticity of concrete (5)	n
of rupture (5)	R
section (5)	Z or S
Molecular weight (3)	M
Moment	
of any area about a given axis, statical (5)	Q
of force, including bending moment (5)	M
in inch-pounds at any section of a girder due to the moment of 1 in-lb applied to the girder at any point (5)	m
of inertia, polar (5)	J
of inertia, rectangular (5)	I
Moments	
absolute coefficients of	
pitching (1)	C_M
rolling (1)	C_L
yawing (1)	C_N
of inertia about axes	
longitudinal (1)	A
lateral (1)	B
normal (1)	C
pitching (1)	M
rolling (1)	L
yawing (1)	N
Mutual inductance (2)	M
Neutral axis, distance to extreme fiber (5)	c
Number of conductors or turns (2)	N
Number of revolutions per unit of time (5)	n
Period (2) (5)	T
Permeability (2)	μ
Permeance (2)	$\mathcal{P}$
Permittance (2)	C
Permittivity (2)	K or ϵ
Phase displacement (2)	θ or ϕ
Pitch	
angle of (1)	θ
ratio, effective (1)	$\frac{V}{ND}$
Potential	
electric †‡ (2)	E, e
function, internal; Helmholtz' free energy (3)	ψ
function, total; Gibbs' function (3)	z or ζ
Power (2)	P, p
Power (1) (3) (4) (5)	P
at brake (4)	P_B
coefficients	
$\frac{P}{\rho N^3 D^5}$ (1)	C_P
$\frac{P}{\rho V^3 D^2}$ (1)	C_P'
$\frac{P}{\rho V^5/N^2}$ (1)	C_P''
of turbine under 1-ft head (4)	P_1
from water (4)	P_W
Pressure	
intensity; force per unit area (1) (3) (4) (5)	p
center of (1)	c.p.
coefficient of center of (1)	C_p
dynamic (or impact) (1)	q
mean effective (3)	p_m
saturation (3)	p_f, p_g
Quality of steam (3)	x
Quantity	
of electricity (2)	Q, q
total, of a fluid, water, gas, heat (by volume) (3)	Q
of light (6)	Q
per unit time (3)	q

Table 4. Symbols for Physical Quantities—*Continued*

NAME OF QUANTITY	SYMBOL
Radiant flux (6)	Φ
Radius (3) (5)	r
of curvature (5)	ρ
of gyration (5)	k
hydraulic (4)	R
to any point from center of runner or impeller (4)	r
Ratio	
of the distance from the neutral axis to the outer fiber of a reinforced-concrete beam to the distance from the outer fiber to the point of application of the resultant tensile stress (5)	k
of the lever arm of the resisting couple in a reinforced-concrete beam to the distance between the outer compressive fiber and the point of application of the resultant tensile stress (5)	j
of peripheral speed of runner to $\sqrt{2gH}$ (4)	ϕ
Reactance (2)	X, x
Reactions (5)	R
Reflection factor (6)	ρ
Reluctance (2)	$\mathcal{R}$
Reluctivity (2)	ν
Resistance	
electrical (2)	R, r
thermal (3)	R
Resistivity	
electrical (2)	ρ
thermal (3)	$\frac{1}{k}$
Revolutions per minute under 1-ft head (4)	n_1
Revolutions per unit time (3) (4) (5)	n
Reynolds' number (1)	$\rho \frac{Vl}{\mu}$
Roll or bank, angle of (1)	ϕ
Rotation	
center of (5)	O
rate of, propeller (1)	N
speed of (2)	n
Rupture, modulus of (5)	R
Saturation pressure (3)	p_f, p_g
Saturation temperature (3)	t_f, T_f or t_g, T_g
Section modulus (5)	Z or S
Self-inductance (2)	L
Set of control surfaces, angle of * (1)	δ
Slip-stream velocity (1)	V_s
Slope, hydraulic (4)	S
Span (1)	b
Specific	
heat (3)	c
heat at constant pressure (3)	c_p
heat at constant volume (3)	c_v
heats, ratio of (3)	κ or k
speed or type characteristic (4)	n_s
volume (3)	v
Speed	
air (1)	V
air, indicated (1)	V_i
of rotation (2)	n
specific (4)	n_s
Stabilizer setting with reference to lower wing, angle of (1)	β
Statical moment of any area about a given axis (5)	Q
Steel ratio, in reinforced-concrete beams (5)	p
Stress	
total compressive or total concrete, in reinforced concrete (5)	C
total shear (5)	V
total tensile or total steel in reinforced concrete (5)	T
unit (5)	s
unit compressive (5)	s_c
unit concrete, in reinforced concrete (5)	f_c
unit shear (5)	s_s
unit shear of concrete (5)	v
unit steel, in reinforced concrete (5)	f_s
unit tensile (5)	s_t
Susceptance (2)	b

Table 4. Symbols for Physical Quantities—*Continued*

NAME OF QUANTITY	SYMBOL
Temperature	
absolute ‖ (F abs or K) (3) (5)	T or Θ
ordinary ‖ (F or C) (3) (5)	t or θ
saturation (3)	t_f, T_f or t_g, T_g
Thermal	
conductance (3)	C
conductance per unit area; " unit conductance " (3)	C_A
conductivity (3)	k
resistance (3)	R
resistivity (3)	$\frac{1}{k}$
transmission (3)	q
Thickness (5)	d or t
Thrust (1)	T
coefficients	
$\frac{T}{\rho N^2 D^4}$ (1)	C_T
$\frac{T}{\rho V^2 D^2}$ (1)	$C_T{}'$
$\frac{T}{\rho V^4 / N^2}$ (1)	$C_T{}''$
Time (4) (5)	t
Time ¶ (3)	t or τ
Torque (1)	Q
coefficients	
$\frac{Q}{\rho N^2 D^5}$ (1)	C_Q
$\frac{Q}{\rho V^2 D^3}$ (1)	$C_Q{}'$
$\frac{Q}{\rho V^5 / N^3}$ (1)	$C_Q{}''$
Torque (5)	T
Transmission	
factor (6)	τ
thermal (3)	q
Vaporization, heat of, at constant pressure (3)	L or h_{fg}
Velocity (3) (4)	V
Velocity (5)	V or v
of approach, weirs (4)	v_0
angular (1) (2) (3) (4) (5)	ω
absolute, of the water at any point in a rotating runner or impeller (4)	V
circumferential, of a point on a rotating runner or impeller (4)	u
circumferential or tangential component of absolute, of the water (4)	V_u
coefficient of (4)	c_v
meridional component of the absolute, of the water (4)	V_m
of moving casing (4)	u
radial component of the absolute, of the water (4)	V_r
relative to moving casing (4)	v
relative velocity of the water with respect to the moving runner or impeller (4)	v
slip-stream (1)	V_s
Velocities	
angular	
roll (1)	p
pitch (1)	q
yaw (1)	r
linear	
roll (1)	u
pitch (1)	v
yaw (1)	w
Viscosity	
absolute; coefficient of (1) (3) (4)	μ
kinematic (1) (3) (4)	ν
relative (to absolute viscosity of water) (3)	Z
relative kinematic (3)	use $\frac{\nu}{\nu_w}$
Visibility factor (6)	K
Voltage † (2)	E, e

Table 4. Symbols for Physical Quantities—*Continued*

NAME OF QUANTITY	SYMBOL
Volume (5)	V
specific (3)	v
total (3)	V
per unit time (3)	q
Weight	
molecular (3)	M
rate; per unit of power; for unit of time (3)	w
total (1) (3)	W
per unit time (4)	W
per unit time per unit area of cross-section; "mass velocity" (3)	G
per unit volume (4)	w
Width, channel surface (4)	B
Wing setting angle of (angle between the wing chord and the thrust line) (1)	i_w
Work (2) (3) (5)	W
per unit weight (3)	w
heat equivalent of (3),	$\frac{1}{J}$ or A
Yaw, angle of (1)	ψ

* Use with appropriate subscript.

† Where distinctions between maximum, instantaneous, effective (root-mean-square), and average values are necessary, E_m I_m P_m are recommended for maximum values; e, i, p for instantaneous values; E, I for effective (rms) values; and P for average value.

‡ Where a distinction between electromotive force and difference of electric potential is desirable, the symbols E, e, and V, v, respectively, may be used.

§ Capital letters denote total quantities, and small letters, specific quantities, or quantity per unit.

‖ θ and Θ in source (3) only. θ is preferably used only when t is used for time in the same discussion. Θ is preferably used only when θ is used for ordinary temperature.

¶ τ should be used only when t is used for ordinary temperature in the same discussion.

MATHEMATICAL TABLES

Table 5. Certain Constants Containing e and π

$e = 2.7182818285$ $\qquad M = \log_{10} e = 0.4342944819$

Table 10. Common Logarithms of Numbers

Mantissas in Six Decimal Places

The common logarithm of a number is the index of the power to which the base 10 must be raised in order to equal the number.

The common logarithm of every positive number not an integral power of 10 consists of an *integral* and a *decimal part.* The integral part or whole number is called the *characteristic* and may be either *positive or negative.* The decimal or fractional part is a *positive* number called the *mantissa* and is the same for all numbers which have the same sequential digits.

The characteristic of the logarithm of any positive number greater than one is positive and is one less than the number of digits before the decimal point.

The characteristic of the logarithm of any positive number less than one is negative and is one more than the number of ciphers immediately after the decimal point.

A negative number or number less than zero has no real logarithm.

EXAMPLES: $\mathrm{Log}_{10}\, 25400. = 4.404834$ $\mathrm{Log}_{10}\, 0.0254 = \bar{2}.404834$ or $8.404834 - 10$

The two systems of logarithms in general use are the common or Briggsian logarithms, introduced in 1615 by Henry Briggs, a contemporary of John Napier, the inventor of logarithms, and the natural or less appropriately termed Napierian or hyperbolic logarithms, which developed somewhat accidentally from Napier's original work. The latter have a base denoted by e, an irrational number, which is:

$$\mathrm{Lim}_{u \to \infty}\left(1+\frac{1}{u}\right)^{u} \qquad 1+1+\frac{1}{2!}+\frac{1}{3!}+\frac{1}{4!}+ \qquad 2.7182818$$

To obtain the natural logarithm, the common logarithm is multiplied by $\log_e 10$ which is 2.302585, or $\log_e N = 2.302585 \log_{10} N$.

Table 11. Natural (Napierian) Logarithms of Numbers

The natural logarithm of a number is the index of the power to which the base e ($= 2.7182818$) must be raised in order to equal the number.

Example: $\log_e 4.12 = \ln 4.12 = 1.4159$.

The table gives the natural logarithms of numbers from 1.00 to 9.99 directly, and permits the finding of the logarithms of numbers outside of that range by the addition or subtraction of the natural logarithms of powers of 10.

Examples: $\log_e 679. = \log_e 6.79 + \log_e 10^2 = 1.9155 + 4.6052 = 6.5207.$
$\log_e .0679 = \log_e 6.79 - \log_e 10^2 = 1.9155 - 4.6052 = -2.6897.$

Natural Logarithms of Powers of 10

$\log_e 10 = 2.302\,585$
$\log_e 10^2 = 4.605\,170$
$\log_e 10^3 = 6.907\,755$
$\log_e 10^4 = 9.210\,340$
$\log_e 10^5 = 11.512\,925$
$\log_e 10^6 = 13.815\,511$
$\log_e 10^7 = 16.118\,096$
$\log_e 10^8 = 18.420\,681$
$\log_e 10^9 = 20.723\,266$

To obtain the common logarithm, the natural logarithm is multiplied by $\log_{10} e$, which is 0.434 294, or $\log_{10} N = 0.434\,294 \log_e N$.

A negative number or number less than zero has no real logarithm.

Table 18. Values and Logarithms of Exponentials and Hyperbolic Functions

The following tables give values of e^x, e^{-x}, sinh x, cosh x and tanh x for values of x from 0.00 to 6.00 in intervals of 0.01.

To facilitate computations involving multiplication, the common logarithms of e^x, sinh x, cosh x, and tanh x are also given.

For values of x greater than 6: e^x may be computed from the relationship $e^x = \log^{-1}(x \log_{10} e) = \log^{-1} 0.43429x$; e^{-x} approaches zero; sinh x and cosh x are approximately equal and become $0.5\,e^x$; and tanh x and coth x have values approximately equal to unity.

Where more accurate values of the exponentials and functions are required they may be computed from the following relationships.

$$e = 2.71828\ 18285 \qquad \frac{1}{e} = 0.36787\ 94412$$

$$M = \log_{10} e = 0.43429\ 44819 \qquad \frac{1}{M} = \log_e 10 = 2.30258\ 50930$$

$$e^x = \log^{-1} Mx \qquad e^{-x} = \log^{-1} - Mx$$

$$\text{Sinh } x = \frac{e^x - e^{-x}}{2} \qquad \text{cosh } x = \frac{e^x + e^{-x}}{2} \qquad \text{tanh } x = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

$$\text{csch } x = \frac{1}{\text{sinh } x} \qquad \text{sech } x = \frac{1}{\text{cosh } x} \qquad \text{coth } x = \frac{1}{\text{tanh } x}$$

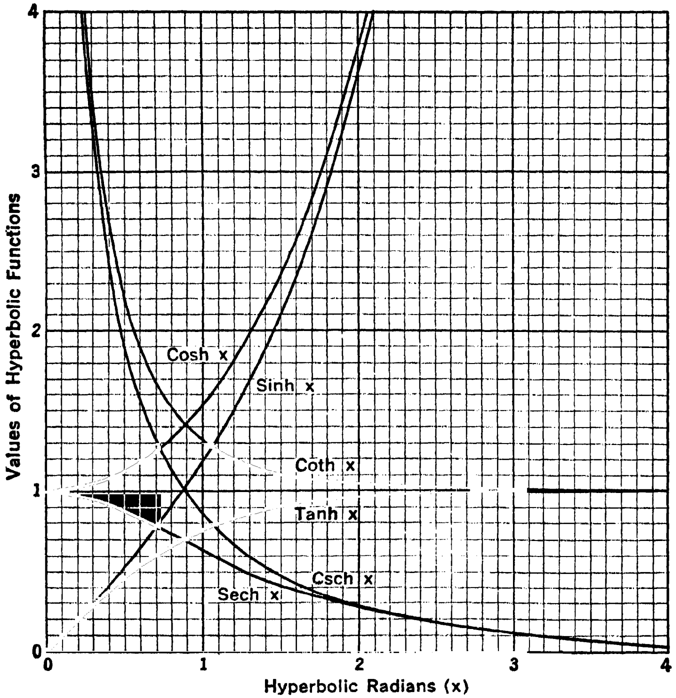

Chart of the Hyperbolic Functions.

Table 19. Table of Integrals

Elementary Indefinite Integrals

1. $\int a\,dx = ax + c$
2. $\int (u + v + w + \ldots)dx = \int u\,dx + \int v\,dx + \int w\,dx + \ldots$
3. $\int u\,dv = uv - \int v\,du$, integration by parts
4. $\int f(x)\,dx = \int f[\phi(y)]\phi'(y)dy,\ x = \phi(y)$, change of variable
5. $\int x^n\,dx = \dfrac{x^{n+1}}{n+1} + c,\ (n \neq -1)$
6. $\int \dfrac{dx}{x} = \log_e x + c = \log_e c_1 x,\ [\log_e x = \log_e(-x) + (2k+1)\pi i]$
7. $\int e^{ax}\,dx = \dfrac{1}{a}e^{ax} + c$
8. $\int a^x\,dx = \dfrac{a^x}{\log_e a} + c$
9. $\int a^x \log_e a\,dx = a^x + c$
10. $\int \sin ax\,dx = -\dfrac{1}{a}\cos ax + c$
11. $\int \cos ax\,dx = \dfrac{1}{a}\sin ax + c$
12. $\int \tan ax\,dx = -\dfrac{1}{a}\log_e \cos ax + c = \dfrac{1}{a}\log_e \sec ax + c$
13. $\int \cot ax\,dx = \dfrac{1}{a}\log_e \sin ax + c = -\dfrac{1}{a}\log_e \csc ax + c$
14. $\int \sec ax\,dx = \dfrac{1}{a}\log_e(\sec ax + \tan ax) + c = \dfrac{1}{a}\log_e \tan\left(\dfrac{ax}{2} + \dfrac{\pi}{4}\right) + c$
15. $\int \csc ax\,dx = \dfrac{1}{a}\log_e(\csc ax - \cot ax) + c = \dfrac{1}{a}\log_e \tan\dfrac{ax}{2} + c$
16. $\int \dfrac{dx}{\sqrt{a^2 - x^2}} = \sin^{-1}\dfrac{x}{a} + c = -\cos^{-1}\dfrac{x}{a} + c\quad (x^2 < a^2)$
17. $\int \dfrac{dx}{a^2 + x^2} = \dfrac{1}{a}\tan^{-1}\dfrac{x}{a} + c = -\dfrac{1}{a}\cot^{-1}\dfrac{x}{a} + c$
18. $\int \sinh ax\,dx = \dfrac{1}{a}\cosh ax + c$
19. $\int \cosh ax\,dx = \dfrac{1}{a}\sinh ax + c$
20. $\int \tanh ax\,dx = \dfrac{1}{a}\log_e(\cosh ax) + c$
21. $\int \coth ax\,dx = \dfrac{1}{a}\log_e(\sinh ax) + c$
22. $\int \operatorname{sech} ax\,dx = \dfrac{1}{a}\sin^{-1}(\tanh ax) + c$
23. $\int \operatorname{csch} ax\,dx = \dfrac{1}{a}\log_e\left(\tanh\dfrac{ax}{2}\right) + c$
24. $\int \sin^2 ax\,dx = \dfrac{1}{2}x - \dfrac{1}{2a}\sin ax \cos ax + c = \dfrac{1}{2}x - \dfrac{1}{4a}\sin 2ax + c$
25. $\int \cos^2 ax\,dx = \dfrac{1}{2}x + \dfrac{1}{2a}\sin ax \cos ax + c = \dfrac{1}{2}x + \dfrac{1}{4a}\sin 2ax + c$

155. $\int xe^{ax}\,dx = \frac{e^{ax}}{a^2}(ax - 1)$

156. $\int x^n b^{ax}\,dx = \frac{x^n b^{ax}}{a\log_e b} - \frac{n}{a\log_e b}\int x^{n-1} b^{ax}\,dx$ (n positive)

157. $\int x^n e^{ax}\,dx = \frac{1}{a}x^n e^{ax} - \frac{n}{a}\int x^{n-1} e^{ax}\,dx$ (n positive)

158. $\int \frac{dx}{b + de^{ax}} = \frac{1}{ab}\left[ax - \log_e (b + de^{ax})\right]$

159. $\int \frac{e^{ax}\,dx}{b + de^{ax}} = \frac{1}{ad}\log_e (b + de^{ax})$

160. $\int \frac{dx}{be^{ax} + de^{-ax}} = \frac{1}{a\sqrt{bd}}\tan^{-1}\left(e^{ax}\sqrt{\frac{b}{d}}\right)$ (b and d positive)

161. $\int \frac{e^{ax}}{x}\,dx = \log_e x + ax + \frac{(ax)^2}{2\cdot 2!} + \frac{(ax)^3}{3\cdot 3!} + \cdots$

162. $\int \frac{e^{ax}}{x^n}\,dx = \frac{1}{n-1}\left(-\frac{e^{ax}}{x^{n-1}} + a\int \frac{e^{ax}}{x^{n-1}}\,dx\right)$ (n integer > 1)

163. $\int e^{ax}\sin bx\,dx = \frac{e^{ax}}{a^2+b^2}(a\sin bx - b\cos bx)$

164. $\int e^{ax}\cos bx\,dx = \frac{e^{ax}}{a^2+b^2}(a\cos bx + b\sin bx)$

165. $\int xe^{ax}\sin bx\,dx = \frac{xe^{ax}}{a^2+b^2}(a\sin bx - b\cos bx)$

$- \frac{e^{ax}}{(a^2+b^2)^2}[(a^2 - b^2)\sin bx - 2ab\cos bx]$

166. $\int xe^{ax}\cos bx\,dx = \frac{xe^{ax}}{a^2+b^2}(a\cos bx + b\sin bx)$

$- \frac{e^{ax}}{(a^2+b^2)^2}\left[(a^2 - b^2)\cos bx + 2ab\sin bx\right]$

Some Definite Integrals

1. $\displaystyle\int_0^a \sqrt{a^2 - x^2}\,dx = \frac{\pi a^2}{4}$

2. $\displaystyle\int_0^a \sqrt{2\,ax - x^2}\,dx = \frac{\pi a^2}{4}$

3. $\displaystyle\int_0^\infty \frac{dx}{a + bx^2} = \frac{\pi}{2\sqrt{ab}}$ (*a* and *b* positive)

4. $\displaystyle\int_0^{\sqrt{a/b}} \frac{dx}{a + bx^2}\,dx = \int_{\sqrt{a/b}}^\infty \frac{dx}{a + bx^2} = \frac{\pi}{4\sqrt{ab}}$ (*a* and *b* positive)

5. $\displaystyle\int_0^{\sqrt{a/b}} \frac{dx}{\sqrt{a - bx^2}} = \frac{\pi}{2\sqrt{b}}$ (*a* and *b* positive)

6. $\displaystyle\begin{aligned}\int_0^\infty \frac{\sin bx}{x}\,dx &= \frac{\pi}{2} && (b > 0)\\ &= 0 && (b = 0)\\ &= -\frac{\pi}{2} && (b < 0)\end{aligned}$

7. $\displaystyle\int_0^\infty \frac{\tan x}{x}\,dx = \frac{\pi}{2}$

8. $\displaystyle\int_0^{\pi/2} \sin^{2n+1} x\,dx = \int_0^{\pi/2} \cos^{2n+1} x\,dx = \frac{2\cdot 4\cdot 6\cdot \ldots \cdot 2n}{3\cdot 5\cdot 7\cdot \ldots \cdot (2n+1)}$ $(n > 0)$

9. $\displaystyle\int_0^{\pi/2} \sin^{2n} x\,dx = \int_0^{\pi/2} \cos^{2n} x\,dx = \frac{1\cdot 3\cdot 5\cdot \ldots \cdot (2n-1)}{2\cdot 4\cdot 6\cdot \ldots \cdot 2n}\cdot\frac{\pi}{2}$ $(n > 0)$

10. $\displaystyle\int_0^\pi \sin ax \sin bx\,dx = \int_0^\pi \cos ax \cos bx\,dx = 0$ $(a \neq b)$

11. $\displaystyle\int_0^\pi \sin^2 ax\,dx = \int_0^\pi \cos^2 ax\,dx = \frac{\pi}{2}$

12. $\displaystyle\int_0^{\pi/2} \log_e \cos x\,dx = \int_0^{\pi/2} \log_e \sin x\,dx = -\frac{\pi}{2}\log_e 2$

13. $\displaystyle\int_0^\infty e^{-ax^2}\,dx = \frac{1}{2}\sqrt{\frac{\pi}{a}}$

14. $\displaystyle\int_0^\infty x^n e^{-ax}\,dx = \frac{n!}{a^{n+1}}$ $(a > 0,\ n = 1, 2, 3, \ldots)$

15. $\displaystyle\int_0^1 \frac{\log_e x}{1 - x}\,dx = -\frac{\pi^2}{6}$

16. $\displaystyle\int_0^1 \frac{\log_e x}{1 + x}\,dx = -\frac{\pi^2}{12}$

17. $\displaystyle\int_0^1 \frac{\log_e x}{1 - x^2}\,dx = \frac{\pi^2}{8}$

PHYSICAL PROPERTIES OF MATERIALS

By H. C. Knutson

Table 20. Properties of Gases

(All properties are at a pressure equivalent to 760 mm of mercury unless otherwise stated)

Miles	6.214×10^{-6}	1.894×10^{-4}	1.578×10^{-5}	0.6214	1.1516	6.214×10^{-4}		1	6.214×10^{-7}	5.682×10^{-4}
Millimeters	10	304.8	25.40	10^6		1000	2.540×10^{-2}		1	914.4
Yards	1.094×10^{-2}	0.3333	2.778×10^{-2}	1094	2027	1.094	2.778×10^{-5}	1760	1.094×10^{-3}	1

Metric Multiples

10^6 microns = 10^3 millimeters = 10^2 centimeters = 10 decimeters = 1 meter = 10^{-1} dekameter = 10^{-2} hectometer = 10^{-3} kilometer = 10^{-4} myriameter = 10^{-6} megameter = 10^{10} Angstrom Units.

Land Measure

7.92 inches = 1 link
25 links = 1 rod = 16.5 feet = 5.5 yards (1 rod = 1 pole = 1 perch)
4 rods = 1 chain (Gunther's) = 66 feet = 22 yards = 100 links
10 chains = 1 furlong = 660 feet = 220 yards = 1000 links = 40 rods
8 furlongs = 1 mile = 5280 feet = 1760 yards = 8000 links = 320 rods = 80 chains

Ropes and Cables

2 yards = 1 fathom
120 fathoms = 1 cable's length

Nautical Measure

6080.27 feet = 1 nautical mile = 1.15156 statute miles
3 nautical miles = 1 league (U. S.)
3 statute miles = 1 league (Gr. Britain)

(NOTE. A nautical mile is the length of a minute of longitude of the earth at the equator at sea level. The British Admiralty uses the round figure of 6080 feet. The word " knot " is used to denote " nautical miles per hour.")

Miscellaneous

3 inches = 1 palm
4 inches = 1 hand
9 inches = 1 span
2 1/2 feet = 1 military pace

Table 28. Area $[L^2]$

Multiply Number of → by → to Obtain ↓	Acres	Circular mils	Square centimeters	Square feet	Square inches	Square kilometers	Square meters	Square miles	Square millimeters	Square yards
Acres	1			2.296×10^{-5}		247.1	2.471×10^{-4}	640		2.066×10^{-4}
Circular mils		1	1.973×10^{5}	1.833×10^{8}	1.273×10^{6}		1.973×10^{9}		1973	
Square centimeters		5.067×10^{-6}	1	929.0	6.452	10^{10}	10^{4}	2.590×10^{10}	0.01	8361
Square feet	4.356×10^{4}		1.076×10^{-3}	1	6.944×10^{-3}	1.076×10^{7}	10.76	2.788×10^{7}	1.076×10^{-5}	9
Square inches	6,272,640	7.854×10^{-7}	0.1550	144	1	1.550×10^{9}	1550	4.015×10^{9}	1.550×10^{-3}	1296
Square kilometers	4.047×10^{-3}		10^{-10}	9.290×10^{-8}	6.452×10^{-10}	1	10^{-6}	2.590	10^{-12}	8.361×10^{-7}
Square meters	4047		0.0001	9.290×10^{-2}	6.452×10^{-4}	10^{6}	1	2.590×10^{6}	10^{-6}	0.8361
Square miles	1.562×10^{-3}		3.861×10^{-11}	3.587×10^{-8}		0.3861	3.861×10^{-7}	1	3.861×10^{-13}	3.228×10^{-7}
Square millimeters		5.067×10^{-4}	100	9.290×10^{4}	645.2	10^{12}	10^{6}		1	8.361×10^{5}
Square yards	4840		1.196×10^{-4}	0.1111	7.716×10^{-4}	1.196×10^{6}	1.196	3.098×10^{6}	1.196×10^{-6}	1

Land Measure

30 1/4 square yards = 1 square rod = 272 1/4 square feet
16 square rods = 1 square chain = 484 square yards = 4356 square feet
2 1/2 square chains = 1 rood = 40 square rods = 1210 square yards
4 roods = 1 acre = 10 square chains = 160 square rods
640 acres = 1 square mile = 2560 roods = 102,400 square rods
1 section of land = 1 square mile; 1 quarter section = 160 acres

Architect's Measure

100 square feet = 1 square

Circular Inch and Circular Mil

A circular inch is the area of a circle 1 inch in diameter = 0.7854 square inch
1 square inch = 1.2732 circular inches
A circular mil is the area of a circle 1 mil (or 0.001 inch) in diameter = 0.7854 square mil
1 square mil = 1.2732 circular mils
1 circular inch = 10^6 circular mils = 0.7854×10^6 square mils
1 square inch = 1.2732×10^6 circular mils = 10^6 square mils

Metric Multiples

1 square meter = 1 centiare = 10^{-2} are = 10^{-4} hectare
= 10^{-6} square kilometer = 10^{-8} square myriameter

Table 29. Volume [L^3]

Multiply Number of → by to Obtain ↓	Bushels (dry)	Cubic centimeters	Cubic feet	Cubic inches	Cubic meters	Cubic yards	Gallons (liquid)	Liters	Pints (liquid)	Quarts (liquid)

Gallons (liquid)		2.642 $\times 10^{-4}$	7.481	4.329 $\times 10^{-3}$	264.2	202.0	1	0.2642	0.125	0.25
Liters	35.24	0.001	28.32	1.639 $\times 10^{-2}$	1000	764.6	3.785	1	0.4732	0.9464
Pints (liquid)		2.113 $\times 10^{-3}$	59.84	3.463 $\times 10^{-2}$	2113	1616	8	2.113	1	2
Quarts (liquid)......		1.057 $\times 10^{-3}$	29.92	1.732 $\times 10^{-2}$	1057	807.9	4	1.057	0.5	1

Metric Multiples

10 milliliters = 1 centiliter = 0.338 fluid ounce
10 centiliters = 1 deciliter = 0.845 liquid gill
10 deciliters = 1 liter = 1.0567 liquid quarts
10 liters = 1 dekaliter = 2.6417 liquid gallons
10 dekaliters = 1 hectoliter = 2.8375 U. S. bushels
10 hectoliters = 1 kiloliter (or stere) = 28.375 U. S. bushels

Cubic Measure

1 cord of wood = a pile cut 4 feet long, piled 4 feet high and 8 feet on the ground = 128 cubic feet

1 perch of stone = a quantity 1 1/2 feet thick, 1 foot high and 16 1/2 feet long = 24 3/4 cubic feet

(NOTE.—A perch of stone is, however, often computed differently in different localities; thus, in most if not all of the States and Territories west of the Mississippi, stonemasons figure rubble by the perch of 16 1/2 cubic feet. In Philadelphia, 22 cubic feet are called a perch. In Chicago, stone is measured by the cord of 100 cubic feet. Check should be made against local practice.)

Board Measure

In board measure, boards are assumed to be one inch in thickness. Therefore, feet board measure of a stick of square timber = length in feet × breadth in feet × thickness in inches.

Shipping Measure

For register tonnage or measurement of the entire internal capacity of a vessel, it is arbitrarily assumed, to facilitate computation, that:

100 cubic feet = 1 register ton

For the measurement of cargo:

40 cubic feet = 1 U. S. shipping ton = 32.143 U. S. bushels
42 cubic feet = 1 British shipping ton = 32.703 Imperial bushels

Dry Measure

One U. S. Winchester bushel contains 1.2445 cubic feet or 2150.42 cubic inches. It holds 77.601 pounds distilled water at 62° F.

(NOTE.—The above is a *struck* bushel. A *heaped* bushel in general equals 1 $^{1}/_{4}$ struck bushels, although for apples and pears it contains 1.2731 struck bushels = 2737.72 cubic inches.)

One U. S. gallon (dry measure) = $^{1}/_{8}$ bushel and contains 268.8 cubic inches.

(NOTE.—This is not a legal U. S. *dry measure* and therefore is given for comparison only.)

One British Imperial bushel contains 1.2843 cubic feet or 2219.36 cubic inches. It holds 80 pounds distilled water at 62° F.

One British Imperial gallon = $^{1}/_{8}$ Imperial bushel and contains 277.42 cubic inches.

1 Winchester bushel = 0.9694 Imperial bushel
1 Imperial bushel = 1.032 Winchester bushels

Same relations as above maintain for gallons (dry measure)

(NOTE.—1 U. S. gallon (dry) = 1.164 U. S. gallons (liquid)).

U. S. Units

2 pints = 1 quart = 67.2 cubic inches
4 quarts = 1 gallon * = 8 pints = 268.8 cubic inches
2 gallons* = 1 peck = 16 pints = 8 quarts = 537.6 cubic inches
4 pecks = 1 bushel = 64 pints = 32 quarts = 8 gallons* = 2150.42 cubic inches
1 cubic foot contains 6.428 gallons (dry measure)*

Liquid Measure

One U. S. gallon (liquid measure) contains 231 cubic inches. It holds 8.336 pounds distilled water at 62° F.

One British Imperial gallon contains 277.42 cubic inches. It holds 10 pounds distilled water at 62° F.

1 U. S. gallon (liquid) = 0.8327 Imperial gallon
1 Imperial gallon = 1.201 U. S. gallons (liquid)

(NOTE.—1 U. S. gallon (liquid) = 0.8594 U. S. gallon (dry)).

U. S. Units

4 gills = 1 pint = 16 fluid ounces
2 pints = 1 quart = 8 gills = 32 fluid ounces
4 quarts = 1 gallon = 32 gills = 8 pints = 128 fluid ounces
1 cubic foot contains 7.4805 gallons (liquid measure)

Apothecaries' Fluid Measure

60 minims = 1 fluid drachm.
8 drachms = 1 fluid ounce

In the U. S. a fluid ounce is the 128th part of a U. S. gallon, or 1.805 cu in. or 29.58 cu cm. It contains 455.8 grains of water at 62° F. In Great Britain the fluid ounce is 1.732 cu in. and contains 1 ounce avoirdupois (or 437.5 grains) of water at 62° F.

---

* The *gallon* is not a U. S. legal *dry measure.*

* Nautical miles per hour.

The Miner's Inch

(Used in Measuring Flow of Water)

An Act of the California legislature, May 23, 1901, makes the standard miner's inch 1.5 cu ft per minute, measured through any aperture or orifice.

The term Miner's Inch is more or less indefinite, for the reason that California water companies do not all use the same head above the center of the aperture, and the inch varies from 1.36 to 1.73 cu ft per minute, but the most common measurement is through an aperture 2 in. high and whatever length is required, and through a plank 1 1/4 in. thick. The lower edge of the aperture should be 2 in. above the bottom of the measuring-box, and the plank 5 in. high above the aperture, thus making a 6-in. head above the center of the stream. Each square inch of this opening represents a miner's inch, which is equal to a flow of 1.5 cu ft per minute.

* These same conversion factors apply to the *gravitational* units of force having the corresponding names. The dimensions of these units when used as gravitational units of force are MLT^{-2}; see table for *Force*.

† Avoirdupois pounds and ounces.

Metric Multiples

10^{6} micrograms = 10^{3} milligrams = 10^{2} centigrams = 10 decigrams = 1 gram = 10^{-1} dekagram = 10^{-2} hectogram = 10^{-3} kilogram = 10^{-4} myriagram = 10^{-6} megagram

Avoirdupois Weight

(Used Commercially)

27.343 grains = 1 drachm
16 drachms = 1 ounce (oz) = 437.5 grains
16 ounces = 1 pound (lb) = 7000 grains
28 pounds = 1 quarter (qr)
4 quarters = 1 hundredweight (cwt) = 112 pounds
20 hundredweight = 1 gross or long ton *
2000 pounds = 1 net or short ton

(* Note.—The long ton is used by the U. S. custom-houses in collecting duties upon foreign goods. It is also used in freighting coal and selling it wholesale.)

14 pounds = 1 stone; 100 pounds = 1 quintal

Troy Weight

(Used in weighing gold or silver)

24 grains = 1 pennyweight (dwt)
20 pennyweights = 1 ounce (oz) = 480 grains
12 ounces = 1 pound (lb) = 5760 grains

The grain is the same in Avoirdupois, Troy and Apothecaries' weights. A carat, for weighing diamonds = 3.086 grains = 0.200 gram. (International Standard, 1913.)

1 pound troy = .8229 pound avoirdupois
1 pound avoirdupois = 1.2153 pounds troy

Apothecaries' Weight

(Used in compounding medicines)

20 grains = 1 scruple (℈)
3 scruples = 1 drachm (ʒ) = 60 grains
8 drachms = 1 ounce (℥) = 480 grains
12 ounces = 1 pound (lb) = 5760 grains

The grain is the same in Avoirdupois, Troy and Apothecaries' weights.

1 pound apothecaries = 0.82286 pound avoirdupois
1 pound avoirdupois = 1.2153 pounds apothecaries

Tons (short) per square foot	1.058							0.0005	0.072	1

* Definition: One atmosphere (standard) = 76 cm of mercury at 0° C.

† Sometimes called a bar.

‡ To convert height h of a column of mercury at t degrees Centigrade to the equivalent height h_o at 0° C. use $h_o = h\left\{1 - \frac{(m - l)t}{1 + mt}\right\}$ where $m = 0.0001818$ and $l = 18.4 \times 10^{-6}$ if the scale is engraved on brass; $l = 8.5 \times 10^{-6}$ if on glass. This assumes the scale is correct at 0° C; for other cases (any liquid) see International Critical Tables, vol. 1, p. 68.

§ 1 gram per sq cm = 10 kilograms per sq m.

* See note at the bottom of Table 43.

† Mean calorie and Btu used throughout. One gram-calorie = 0.001 kilogram-calorie; one Ostwald calorie = 0.01 kilogram-calorie.

The IT cal, 1000 international steam-table calories, has been defined as the 1/860th part of the international kilowatthour (see *Mechanical Engineering*, Nov., 1935, p. 710). Its value is very nearly equal to the mean kilogram-calorie, 1 IT cal = 1.00037 kilogram-calories (mean). 1 Btu = 251.996 IT cal.

‡ Absolute joule, defined as 10^7 ergs. The international joule, based on the international ohm and ampere, equals 1.0003 absolute joules.

1 Cheval-vapeur = 75 kilogram-meters per second
1 Poncelet = 100 kilogram-meters per second

* The "horsepower" used in these tables is equal to 550 foot-pounds per second by definition. Other definitions are one horsepower equals 746 watts (U. S. and Great Britain) and one horsepower equals 736 watts (continental Europe). Neither of these latter definitions is equivalent to the first; the "horsepowers" defined in these latter definitions are widely used in the rating of electrical machinery.

Ohms (meter, gram) †	$10^{-5}\delta$	0.01δ	$2.540 \times 10^{-2}\delta$	$1.662 \times 10^{-3}\delta$	1

* In this table δ is density in grams per cm^3. The following names, corresponding respectively to those at the tops of columns, are sometimes used: abohms per cm cube; microhms per cm cube; microhms per inch cube; ohms per mil-foot; ohms per meter-gram. The first four columns are headed by units of *volume* resistivity, the last by a unit of *mass* resistivity. The dimensions of the latter are $Q^{-2}L^6T^{-1}$; not these given in the heading of the table.

† One ohm (meter, gram) = 5710 ohms (mile, pound).

Table 52. Electric Conductivity * $[M^{-1}Q^2L^{-3}T]$ or $[F^{-1}Q^2L^{-2}T^{-1}]$

Webers per square inch	6.452×10^{-8}	10^{-8}	6.452	1

* The name "gauss" is sometimes used for the unit of magnetic field intensity (1 gauss = 1 gilbert per cm). Since flux density = permeability × field intensity ($B = \mu H$) these two quantities have the same units if μ is considered dimensionless, just as 1 abhenry = $\mu \times 1$ cm; hence the occasional name centimeter for an abhenry. The A.I.E.E. sanctions "gauss" for both B and H; physicists usually do not. In 1930 the International Electrotechnical Commission, of which the U. S. National Committee is the electrical standards committee of the American Standards Association, adopted the following names for units in the cgs electromagnetic system: Magnetomotive force, gilbert; magnetizing force, oersted; magnetic flux, maxwell; magnetic flux density, gauss. The name oersted has been used for a unit of reluctance in the U. S.

Table 57. Magnetic Potential and Magnetomotive Force $[QT^{-1}]$

Multiply Number of → by to Obtain ↓	Abampere-turns	Ampere-turns	Gilberts
Abampere-turns	1	0.1	7.958×10^{-2}
Ampere-turns	10	1	0.7958

Table 58. Magnetic Field Intensity, Potential Gradient and Magnetizing Force $[QL^{-1}T^{-1}]$

Multiply Number of → by to Obtain ↓	Abampere-turns per centimeter	Ampere-turns per centimeter	Ampere-turns per inch	Gilberts per centimeter *
Abampere-turns per centimeter	1	0.1	3.937×10^{-2}	7.958×10^{-2}
Ampere-turns per centimeter	10	1	0.3937	0.7958
Ampere-turns per inch	25.40	2.540	1	2.021
Gilberts per centimeter	12.57	1.257	0.4950	1

* Called "oersteds" by the I.E.C. (1930). See footnote of Table 56 on "Magnetic Flux Density."

Table 59. Specific Heat $[L^2T^{-2}t^{-1}]$

(t = temperature)

To change specific heat in gram-calories per gram per degree Centigrade to the units given in any line of the following table, multiply by the factor in the last column.

Unit of Heat or Energy	Unit of Mass	Temperature Scale *	Factor
Gram-calories	Gram	Centigrade	1
Kilogram-calories	Kilogram	Centigrade	1
British thermal units	Pound	Centigrade	1.800
British thermal units	Pound	Fahrenheit	1.000
Joules	Gram	Centigrade	4.186
Joules	Pound	Fahrenheit	1055.
Kilowatt-hours	Kilogram	Centigrade	1.163×10^{-3}
Kilowatt-hours	Pound	Fahrenheit	2.930×10^{-4}

* Temperature conversion formulas:

t_c = temperature in Centigrade degrees
t_f = temperature in Fahrenheit degrees.
1 deg fahr = ($\frac{5}{9}$) deg cent.
$t_c = \frac{5}{9}(t_f - 32)$
$t_f = \frac{9}{5}t_c + 32$

Table 60. Thermal Conductivity $[MLT^{-3}t^{-1}]$

(t = temperature)

To convert thermal conductivity, in gram-calories transmitted per second from one face of a cube 1 cm on edge to the opposite face per degree Centigrade temperature difference between these faces, to the units given in any line of the following table, multiply by the factor in the last column.

Units of				Temperature Scale	Factor
Heat	Area	Thickness	Time		
Gram-calories	cm^2	cm	second	Centigrade	1
Kilogram-calories	m^2	cm	hour	Centigrade	3.6×10^4
British thermal units	ft^2	inch	hour	Fahrenheit	2903.
Joules	cm^2	cm	second	Centigrade	4.186
Joules	ft^2	inch	second	Fahrenheit	850.6
Kilowatt-hours	m^2	cm	hour	Centigrade	41.86
Kilowatt-hours	ft^2	inch	hour	Fahrenheit	0.8506

GAGES

By J. G. Brainerd

Sheet Metal Gages

The important sheet metal gages in use in the United States are: the United States Standard Gage for sheet and plate iron and steel, the American Wire Gage (also called the Brown and Sharpe W.G.) for copper, aluminum, and brass and other non-ferrous alloys, the Tin Plate Gage, the Galvanized Sheet Gage, the American Zinc Gage, and the Birmingham Wire (or Stubs' Iron Wire) Gage. In Canada and England the Birmingham Gage (different from the Birmingham Wire Gage) and the Imperial Standard Wire Gage (S.W.G.) are used. Still other gages are used elsewhere. In Japan standard thickness of sheet metal is denoted by the thickness in millimeters. A standard Decimal Gage, in which the standard thicknesses are denoted by decimal parts of an inch and not by gage numbers, has been used in the United States. Copper sheets may be obtained with thicknesses any integral multiple of $^1/_{16}$ of an inch up to 2 inches. Heavy copper sheets may be obtained in definite weights per square foot. Each ounce of weight is equivalent to approximately 0.001352 inch thickness. Lead is usually ordered in this manner, each pound being equivalent to approximately 0.017 inch thickness.

The United States Standard Gage for sheet iron and steel (Act of Congress, March 3, 1893; formerly the legal standard for duties) is a *weight* gage based on a density for wrought iron of 480 pounds per cubic foot. Since 1893, steel (density of 489.6 lb per cu ft) has come into general use. A given gage number of this gage represents a fixed weight per unit area, hence a steel sheet will have a smaller thickness than a wrought iron sheet of the same gage number (but monel metal sheets are rolled to the thickness given for wrought iron without regard to weight, which is about 552.2 lb per cu ft). Practice among steel manufacturers is irregular, some keeping the *thickness* constant for a given gage number irrespective of weight. If this practice is followed, the weight per square foot and per square meter given in the second and third columns of Table 61 will vary, whereas thickness will remain that given for wrought iron.

The American Wire Gage specifies thicknesses without regard to weight. For the basis of this gage see the next section (Wire Gages), where are also given the Birmingham W.G. and the S.W.G.

Tables of Thickness and Weight corresponding to United States Standard gage and American Wire gage numbers are shown in Tables 61 and 62. These tables are taken from Circular No. 391 of the Bureau of Standards, in which are given all the gages mentioned above and the tolerances customary in commerce. A committee of the American Standards Association is now working (1936) on the standardization of sheet metal gages.

Table 61. United States Standard Gage * for Sheet and Plate Iron and Steel, and Its Extension †

Gage No.	Weight per square foot		Weight per square meter	Approximate thickness			
				Wrought iron 480 lb/ft³		Steel and open-hearth iron 489.6 lb/ft³

---

* For the Galvanized Sheet Gage, add 2.5 ounces to the weight per square foot as given in the table. Gage numbers below 8 and above 34 are not used in the Galvanized Sheet Gage.

† Gage numbers greater than 38 were not in the standard as set up by law, but are in general use.

* Assumed specific gravities or densities in grams per cubic centimeter; Copper, 8.89; Aluminum, 2.71; brass, 8.47.

Wire Gages

The sizes of wires having a diameter less than $1/2$ inch are usually stated in terms of certain arbitrary scales called "gages." The size or gage number of a solid wire refers to the cross-section of the wire perpendicular to its length; the size or gage number of a stranded wire refers to the total cross-section of the constituent wires, irrespective of the pitch of the spiraling. Larger wires are usually described in terms of their area expressed in circular mils. A circular mil is the area of a circle 1 mil in diameter, and the area of any circle in circular mils is equal to the square of its diameter in mils.

There are a number of wire gages in use, the principal ones being the following:

American or Brown and Sharpe Wire Gage.—This gage is the one commonly used in the United States for copper, aluminum and resistance wires. The gage is designated by either of the abbreviations A.W.G. or B. & S.

Basis of the A.W.G. or B. & S. Gage.—The diameters of wires having successive numbers on this gage are in the ratio of $\sqrt[39]{92}$ (= 1.1229 approx.) to 1, and the No. 36 wire has a diameter of 5 mils. No. 35 A.W.G., therefore, has a diameter of $5 \times 1.1229 = 5.61$ mils and so on until No. 0000 is reached, having a diameter of 460 mils.

The ratio $\sqrt[39]{92}$ is approximately equal to $\sqrt[6]{2}$, which is 1.1225. This circumstance makes it possible to have a group of wires of regular gage size with an aggregate area approximately equal to that of another regular gage size. For example, a reduction of three gage numbers (as from gage No. 36 to No. 33) results in a new gage number representing a diameter approximately $\sqrt{2}$ times that represented by the original gage number—or an area approximately two times as great.

The following approximate relations are also useful:

An increase of 1 in the number increases the resistance 25 per cent.
An increase of 2 in the number increases the resistance 60 per cent.
An increase of 3 in the number increases the resistance 100 per cent.
An increase of 10 in the number increases the resistance 10 times.

A No. 10 A.W.G. copper wire has the following approximate characteristics:

Ohms per 1000 feet	1
Circular mils area	10,000
Weight, pounds per 1000 feet	32

A No. 10 A.W.G. aluminum wire has the following approximate characteristics:

Ohms per 1000 feet	1.6
Circular mils area	10,000
Weight, pounds per 1000 feet	9.5

Remembering these rules it is easy to find the approximate size, resistance, area, or weight of any size wire. For example, a No. 12 A.W.G. copper wire has a resistance of 1 plus 60 per cent = 1.6 ohms per 1000 ft approximately. Its area, being inversely as its resistance, is $10{,}000/1.6 = 6250$ circular mils; its diameter is therefore $\sqrt{6250} = 79$ mils and its weight, $32/1.6 = 20$ pounds per 1000 feet.

U. S. Steel Wire Gage.—This gage, known also as the "Washburn and Moen," "Roebling," "American Steel and Wire Co.'s gage," is the one usually employed in the United States for steel and iron wire. It is frequently abbreviated "S.W.G.," but to avoid confusion with the British Standard Wire Gage (*see below*) it should be abbreviated "Stl. W.G." or "A. (steel) W.G."

Birmingham (or Stubs' Iron) Wire Gage.—This gage is still used in the United States for some purposes, e.g., to designate the size of brass wire, and is also employed to a limited extent in Great Britain. It is usually abbreviated "B.W.G." It is sometimes referred to as the "Stubs' Iron Wire Gage," but it should not be confused with the Stubs' Steel Wire Gage.

British Standard Wire Gage.—This gage, usually called simply the "Standard Wire Gage," and abbreviated "S.W.G." is also known as the "New British Standard" (abbreviated "N.B.S."), the English Legal Standard, or the Imperial Wire Gage, and is the legal standard of Great Britain for all wires, as fixed by order in Council, August 23, 1883. It was constructed by modifying the Birmingham Wire Gage, so that the differences between successive diameters were the same for short ranges, i.e., so that a graph representing the diameters consists of a series of a few straight lines.

Edison Wire Gage.—The size of a wire on this gage is equal to its cross-sectional area in circular mils divided by 1000. For example, a solid wire 0.2 inch in diameter has the number $(200)^2/1000 = 40$. This gage is now rarely used.

Metric Wire Gage.—The gage number is ten times the diameter in millimeters.

Other Gages.—In addition wire sizes are sometimes specified in terms of the "Old English Wire Gage," known also as the "London Gage," and the "Stubs' Steel Wire Gage." The Old English Wire Gage is the same as B.W.G. for all gage numbers under 20.

Comparison of Wire Gages.—A comparison of the different gages, in terms of the diameters (in mils or thousandths of an inch) of solid wires corresponding to the various numbers, is given in Table 63. The cross-section in circular mils is the square of the diameter in mils.

Table 63. Comparison of Wire Gage Diameters in Mils

(Bureau of Standards, Circulars No. 31 and No. 67)

* For diameters corresponding to metric gage numbers, 1.2, 1.4, 1.6, 1.8, 2.5, 3.5, and 4.5, divide those of 12, 14, etc., by ten.

STANDARD STRUCTURAL SIZES

Steel Sections. Tables 64 to 70 give the dimensions, weights, and properties of *rolled steel* structural sections, including wide-flange sections, American standard beams, channels, angles, tees, and zees. The values for the various structural forms, taken from the January 1934 edition of "Steel Construction," by the kind permission of the publisher, the American Institute of Steel Construction, give the section specifications required in designing steel structures. The theory of design is covered in Section 5.

Most of the sections can be supplied promptly by the Bethlehem, Carnegie, and Illinois Steel Company mills. Owing to variations in the rolling practice of the different mills, their products are not identical, although their divergence from the values given in the tables is practically negligible. For standardization, only the lesser values are given, and therefore they are on the side of safety.

Further information on sections listed in the tables, together with information on other products and on the requirements for placing orders, may be gathered from mill catalogs.

Aluminum Sections. Tables 64 to 70 for structural-steel sections are roughly applicable to aluminum sections with the following reservations:

(a) Aluminum wide-flange beams are not readily available in the large variety of sizes given for steel sections. The aluminum beams coming closest to the wide flange steel beams are a short series of "H" beams in sizes 4 × 4, 5 × 5, 6 × 6, and 8 × 8. For the specifications of this series see the catalog of any aluminum rolling mill.

(b) In the other shapes of beams, sizes approximating the following steel sizes are available in aluminum.

1. American standard beams; 12 × 5 $^1/_4$, 12 × 5, and 10 × 4 $^3/_4$.
2. Channels; 12 × 3, 10 × 2 $^5/_8$, 9 × 2 $^1/_2$, and 8 × 2 $^1/_4$.
3. Angles with equal legs; most sizes up to and including 6 × 6, in thicknesses up to $^3/_4$ in.
4. Angles with unequal legs; most sizes up to and including 6 × 4, in thicknesses up to $^3/_4$. in.
5. Tees; almost all sizes.
6. Zees; almost all sizes.

(c) The tabulated values for steel sections, with the exception of weight, may be used in approximate calculations for aluminum sections since there is usually less than 2 per cent difference between the aluminum and steel values. In most cases the aluminum value is slightly higher and therefore on the safe side. On the average, the weights of the aluminum sections are 0.356 the weights of the corresponding steel sections.

For information about other standard aluminum sections and for more accurate values than those corresponding to the steel tables see the catalog of any aluminum rolling mill.

Tee sections are seldom used as structural framing members. When so used they are generally employed on short spans in flexure. In these tables are listed a few selected sizes, the range of whose section moduli will cover all ordinary conditions. For sizes not listed, the catalogs of the respective rolling mills should be consulted.

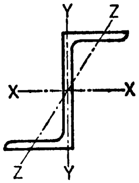

Table 70.

Large O. D. Pipe

Pipe 14″ and larger is sold by actual O. S. diameter and thickness.

Sizes 14″, 15″, and 16″ are available regularly in thicknesses varying by 1/16″ from 1/4″ to 1″, inclusive.

All pipe is furnished random length unless otherwise ordered, viz: 12 to 22 ft with privilege of furnishing 5 per cent in 6 to 12 ft lengths. Pipe railing is most economically detailed with slip joints and random lengths between couplings.

MATHEMATICS

Notation

A Symbol is a letter or sign used to represent a mathematical entity such as a numerical value or an operation. The *notation* for symbols used in this section follows in general the American Standard for Mathematical Symbols (A.E.S.C. report Z 10 f) and (for elementary subjects) the recommendations of the Math. Assoc. of America (Report of Nat. Com., 1923, Chapter 8). The names of letters taken from the Greek alphabet may be found in Table 1, Section 1, and standard mathematical symbols in Table 2, Section 1.

An Abbreviation, as distinguished from a symbol, is a shortened expression for a name or a unit. Abbreviations for engineering terms may be found in Table 3, Section 1. (See also A.S.A. report Z 10 i.)

ARITHMETIC

By Janvier M. Rice

1. NUMBER NOTATION

Notation. Numbers are expressed by *words* and represented by *figure* or *letter* characters. The *figure notation* in common use is the *Arabic,* so called because it was first introduced into Europe by the Arabs. The common *letter notation* is named from the ancient Romans who used it.

Numeration of Arabic Numbers. Any method of naming numbers is called *numeration.* The method in common use is a decimal system in which the figures or *digits* are separated by commas into groups of three figures each, called periods. For example, the number 1,211,024,006,357.089 is read, " one *trillion,* two hundred eleven *billion,* twenty-four *million,* six *thousand,* three hundred fifty-seven, and eighty-nine *thousandths.*"

A whole number is called an *integer.* A number expressed by an *integer* and *fraction* is a *mixed number.*

Roman Notation uses seven letters and a bar; a letter with a bar placed over it represents a thousand times as much as it does without the bar. The letters and rules for combining them to represent numbers are as follows:

I	V	X	L	C	D	M	$\overline{\text{L}}$
1	5	10	50	100	500	1000	50,000

Rule 1. If no letter precedes a letter of greater value, add the numbers represented by the letters.

Example: XXX represents 30; VI represents 6.

Rule 2. If a letter precedes a letter of greater value, subtract the smaller from the greater; add the remainder or remainders thus obtained to the numbers represented by the other letters.

Example: IV represents 4; XL represents 40; CXLV represents 145.

Other Illustrations:

IX	XIII	XIV	LV	XLII	XCVI	MDCI	$\overline{\text{IV}}$CCXL
9	13	14	55	42	96	1601	4240

2. FUNDAMENTAL PROCESSES AND TERMS

Addition is indicated by the sign +, which is read *plus.* The numbers added are called *addends.* The result is called the *sum.*

Subtraction is indicated by the sign −, which is read *minus.* The number subtracted is called the *subtrahend,* and the number from which it is subtracted the *minuend.* The result is called the *remainder* or *difference.*

Multiplication is indicated by the sign ×, which is read *times* or *multiplied by.* The number multiplied is called the *multiplicand,* and the number by which it is multiplied, the *multiplier.* The result is called the *product.*

Division is indicated by the sign ÷, which is read *divided by.* The number divided is called the *dividend,* and the number by which it is divided the *divisor.* The result is called the *quotient.*

The process of division may be indicated also by a *fraction,* the *numerator* of which is the dividend and the *denominator* the divisor.

If the quotient is an *integer* the division is *exact.* If the division is not exact, the part of the dividend that is left is called the *remainder.*

Reciprocals. The reciprocal of a number is 1 divided by the number and, unless the division is exact, may be expressed as a fraction, decimal, or mixed number. Thus the reciprocal of 4 is $^1/_4$ or 0.25. If tables are available, use of reciprocals saves the labor of division if long divisors are involved, as the same result can be obtained by multiplying the dividend by the reciprocal of the divisor. Reciprocals of numbers may be found in Table 7, Section 1.

Percentage. *Per cent* means " by the hundred." To determine the per cent change in a quantity, divide the change in number of units by the original number of units and multiply by 100. For example, if an article costing 80 cents is sold for one dollar, the profit is 20 cents, or 25 per cent of the cost; if it is sold instead for 68 cents, the loss is 12 cents or 15 per cent of the cost.

Combination of Processes. If either × or ÷ occurs in an expression in connection with +, −, or both, the indicated *multiplications* or *divisions* are to be performed first. If both × and ÷ occur and are succeeding signs in any expression, the indicated multiplications and divisions are performed in order from the left. For example:

$$3 + 10 \div 2 \times 4 - 1 = 3 + 5 \times 4 - 1 = 3 + 20 - 1 = 22$$

To avoid confusion, *parentheses* ( ), *brackets* [ ], *braces* { }, and the *vinculum* $\overline{\quad}$, are used as *signs of aggregation* in grouping expressions. Each group being regarded as a single number, operations within groups should be performed first. For example:

$$2 \times \{[10 \div (3 - 1)] + 4 \div \overline{3 - 1}\} = 2 \times \{5 + 4 \div 2\} = 2 \times 7 = 14$$

Factors and Divisors. Integers that multiplied together produce a given number are called *factors* of the number. A whole number that has no factors other than 1 and the number itself is a *prime number.* A number that has factors other than 1 and itself is called a *composite number.*

Integers which are factors of an integer are also called *exact divisors.*

The process of separating a number into its factors is called *factoring.*

Factorials. The multiple product $n(n - 1)(n - 2) \ldots 3 \times 2 \times 1$ is called *factorial n* and written $n!$ Values of $n!$ up to those of 20! are given in Table 6, Section 1.

Greatest Common Divisor. If two or more numbers are divisible by the same number, they are said to have a *common divisor.* The greatest number that will exactly divide all of them is called their greatest common divisor (G.C.D.).

Least Common Multiple. A number that is divisible by each of two or more numbers is a *common multiple* of those numbers. The least number satisfying this condition of divisibility is the *least common multiple* of the numbers (L.C.M.).

Fractions having the same denominator are called *similar* fractions, and those having different denominators *dissimilar* fractions. In adding dissimilar fractions, find the L.C.M. of the denominators, called the *least common denominator,* and change the given fractions to similar fractions having this denominator.

Powers and Roots. A *power* of a number is a product obtained by using the number a certain number of times as a factor. The number of times the number occurs as a factor is called the exponent, and is written at the right of the number and a little above. For example, the second power or square of 3 is 9 and is written $3^2 = 9$. Likewise, the third power or cube of 3 is 27 and is written $3^3 = 27$.

One of the equal factors of a number is called the *root* of the number. In the example above, 3 is the *square root* of 9 and the *cube root* of 27.

The process of finding the root of a number may be indicated by the radical sign or by a fractional exponent of the number.

Example: $9^{1/2} = \sqrt{9} = 3,\ 8^{1/3} = \sqrt[3]{8} = 2.$

3. SQUARE ROOT AND CUBE ROOT

To Extract the Square Root. (1) Point off the given number into periods of two figures each, starting at the decimal point and going both ways.

(2) Find the largest square in the left-hand period and use its root as the first digit of the result; subtract the square from the left-hand period and to the remainder annex the next period for a new dividend.

(3) Double the root already found and annex one zero for a trial-divisor; determine how many times it will go into the dividend, and put the number in the result and also in place of the zero in the divisor. Multiply this completed divisor by the number just placed in the result, subtract the product from the dividend, and to the remainder bring down the next period for a new dividend and proceed as before.

(4) If at any time the product of a new figure in the root by the " completed " divisor is greater than the dividend, erase the new figure from both the result and the divisor, substituting a figure just small enough to make the product of the new figure of the result by the divisor less than or equal to the dividend. If at any time a divisor is not contained in the dividend even once, bring down the next period for a new dividend, annex another zero to the trial divisor, put a zero in the quotient and proceed in the regular manner.

Example:

$$\begin{array}{rl} & 3'02.'98'06'52' \;\big|\; \underline{17.406+} \\ & \underline{1} \\ 27 & 202 \\ & \underline{189} \\ 344 & 1398 \\ & \underline{1376} \\ 34806 & 220652 \\ & \underline{208836} \end{array}$$

To Extract the Cube Root. (1) Point off the given number into periods of three figures, each starting at the decimal point and going both ways.

(2) Find the largest cube in the left-hand period and use its root as the first digit of the result; subtract the cube from the left-hand period and to the remainder annex the next period for a new dividend; square the root already found and multiply by 300 for a trial divisor. Find how many times this trial divisor is contained in the dividend and write the number in the root.

(3) Add together the trial divisor, 30 times the product of the first figure of the root by the second, and the square of the second figure in the root; multiply the sum (which is the completed divisor) by the last figure in the root, and subtract from the dividend.

(4) To the remainder annex the next period and proceed as before to find the third figure of the root—that is, square the two figures of the root already found, multiply by 300 for a trial divisor, etc.

(5) If at any time the product of a new figure in the root by the " completed" divisor is greater than the dividend, erase the new figure from the result and from wherever it appeared in obtaining the divisor, substituting a figure just small enough to make the product of the new figure of the result by the divisor less than or equal to the dividend. If at any time a divisor does not go into the dividend even once, write a zero in the root, annex the next period to the dividend, and proceed in the regular manner.

Example:

$$\begin{array}{rr|l} & & 158'252'.632'929 \;\big|\; \underline{54.09} \\ 5^3 = & & \underline{125} \\ 300 \times 5^2 = & 7500 & 33252 \\ 30 \times 5 \times 4 = & 600 & \\ 4^2 = & \underline{16} & \\ & 8116 & \underline{32464} \\ 300 \times 540^2 = & \overline{87480000} & 788632929 \\ 30 \times 540 \times 9 = & 145800 & \\ 9^2 = & \underline{81} & \\ & 87625881 & \underline{788632929} \end{array}$$

Tables of Square Roots and Cube Roots, as well as squares and cubes, of integers from 1 to 1000 are given in Table 7, Section 1.

To Extract Any Root other than the square root or cube root (and frequently for the latter), logarithms are generally employed. See p. 2-10.

4. APPROXIMATE COMPUTATIONS

Significant Figures

Numerical engineering data are subject to errors of various kinds and should be written so that no ambiguity can exist as to the significance of the figures. In the number 0.002953 it would naturally be understood that four *significant figures*, 2, 9, 5, 3, are intended. In 2,953,000, however, it should be made clear whether the three zeros are in doubt or not. Frequently powers of 10 are used as factors to bring significant figures into prominence. Thus 2,953,000 might be written 2953×10^3; however, this notation does not *necessarily* imply that only the four digits at the left are significant, as this method is sometimes used only to conserve space.

Addition and Subtraction. A doubtful figure in any of the numbers makes the sum or difference in the column in which it lies doubtful. Retain significant figures in the result for only those columns in which all figures are significant. In the example, doubtful figures are indicated by the symbol x.

```
 2.953xx
 0.8942x
 0.06483
 -------
 3.912xx
```

Multiplication. It is convenient to arrange the work so that the figures of the multiplier are used from left to right, since doubtful figures are thus displayed prominently to the right of the vertical line. It is unnecessary to write the doubtful figures. The operation may be abbreviated by dropping the right-hand figures of the multiplicand one by one as multiplication is completed by successive figures of the multiplier, making proper allowance for so doing in the products.

```
  2,953
  4,128
 ------
 11,812 |
    295 | 3
     59 | 06
     23 | 624
 ------ |----
 12,19x | xxx
```

Division. Work may be much abbreviated for numbers with limited significant figures by cutting off one figure of the divisor at each division, instead of adding a doubtful zero from the dividend to the remainder. This method gives rise to no loss in accuracy, and leads quickly to the desired result.

```
 4128) 12190 (2
        8256
  413)  3934 (9
        3717
   41)   217 (5
         205
    4)    12 (3
```

Errors

A definite number of significant figures is usually implied in a numerical table. The last right-hand digit may be in error as much as half a unit. Therefore, in adding numbers taken from a table, errors may accumulate. The last right-hand digit may thus be in error several units, and this fact should be noted carefully in any computation. Similar observations apply to other operations of arithmetic. In general, the result obtained by computing with numerical tables of, say, four significant figures cannot be depended upon beyond three significant figures. Hence to reach a desired degree of accuracy it is essential to carry along one extra figure up to the last step.

The Absolute Error in any approximation is the actual difference between the approximate and the exact value. The limits between which the absolute error lies are usually all that is known of its magnitude. Thus if we take $\sqrt{7} = 2.646$, absolute error lies between -0.0005 and $+0.0005$ (inclusive), i.e., is numerically $\leqq 0.0005$.

The Relative Error is the ratio of absolute error to exact value. Usually in any given case an upper limit only of the relative error is known. Thus, the relative error in $\sqrt{7} = 2.646$ is less than or equal to "1 part in 2×2646."

The Probable Error is that error which is equally likely to be, or not to be, exceeded. Thus for the tabular value of $\sqrt{7} = 2.646$ with an absolute error lying numerically between 0 and 0.0005, the probable error is 0.00025. An interpolated value has a greater probable error owing to the inaccuracy of the fundamental assumption for interpolation (see below).

Simple Theorems on Errors.

(1) In a sum or difference, the absolute error of the result is not greater than the sum of the absolute errors of the given terms.

(2) In a product or quotient, the relative error of the result is not greater than the sum of the relative errors of the terms (practically).

Interpolation in Tables

It is often convenient to consult tables for values which are not directly given, but which may be found by *interpolation by first differences*, as illustrated below. The principle is the same, regardless of the nature of the data involved.

Example: Table 7, Section 1, gives $\sqrt{160} = 12.6491$ and $\sqrt{161} = 12.6886$. Suppose $\sqrt{160.3}$ to be desired. The square root has increased 0.0395 for an increase of 1 unit in the number. Interpolation is based on the *assumption* (not strictly correct) that a change in the number amounting to a fraction of a unit changes its function (in this case the square root) by the same fractional amount of its corresponding total change.* On this basis, $\sqrt{160.3} = 12.6491 + (0.0395 \times 0.3) = 12.6610$.

ALGEBRA

By Janvier M. Rice

5. NUMBERS

Classification of Numbers. The following are examples of number classifications: *positive integers*, 1, 2, 3; *negative integers*, -1, -2, -3; *integers*, all positive and negative integers and zero; *fractions*, $^1/_3$, $-^5/_2$; *rational numbers*, i.e., those which can be expressed as the quotient of two integers, as $^3/_5$, $\sqrt[3]{-^1/_{27}}$; *irrational numbers*, i.e., those which cannot be expressed as the quotient of two integers, as $\sqrt{2}$, π; *real numbers*, i.e., those which are not complex or purely imaginary (see below); *imaginary numbers*, i.e., even roots of negative numbers, as $\sqrt[4]{-3}$, $\sqrt{-1}$ (the symbol i is used for $\sqrt{-1}$) †; *complex numbers* i.e., combinations of real and imaginary numbers, as $(2 + 3\sqrt{-1}) = (2 + 3i)$.

The Absolute Value of a Number is its numerical value without regard to sign, as absolute value of -3 is 3 and is written $|-3|$.

6. FUNDAMENTAL OPERATIONS

Symbols of Operation and Grouping are the same in algebra as in arithmetic except that the omission of a symbol in algebra indicates multiplication whereas in arithmetic it indicates addition. Thus $2\,a/b$ means $2 \times a/b$, whereas $2\,^3/_7$ means $2 + {}^3/_7$.

Grouping. If an expression within parentheses is preceded by a plus sign, the parentheses may be removed. If an expression within parentheses is preceded by a minus sign, the parentheses may be removed if the sign of every term within them is changed. Thus, $2 + (a - b) = 2 + a - b$; and $2 - (a - b) = 2 - a + b$. If parentheses occur within parentheses, these may be removed, in succession, by removing first the innermost parentheses; next, the innermost of all that remain, and so on. Thus:

$$a - [6 + c - (d + 3)] = a - [6 + c - d - 3] = a - [3 + c - d] = a - 3 - c + d$$

Parentheses may be introduced, if desired, by reversing the process.

Addition and Subtraction. Like terms should be combined; the others are simply repeated, preceded by their proper signs. Thus:

$$-2\,ax + 4\,z - (c - 5\,ax + 3\,z) = 3\,ax + z - c$$

Similarly, polynomials are added or subtracted by combining their respective terms. Thus, to add $m^5 - 3\,m^4n - 6\,m^3n^2$, $+ m^3n^2 + m^2n^3 - 5\,m^4n$, and $-n^5 + 2\,m^5 + 7\,m^4n$, write:

$$\begin{array}{rrrrr}
+\ m^5 & -\ 3\,m^4n & -\ 6\,m^3n^2 & & \\
 & -\ 5\,m^4n & +\ m^3n^2 & +\ m^2n^3 & \\
+\ 2\,m^5 & +\ 7\,m^4n & & & -\ n^5 \\
\hline
+\ 3\,m^5 & -\ m^4n & -\ 5\,m^3n^2 & +\ m^2n^3 & -\ n^5
\end{array}$$

Or for subtraction:

$$(a^3x^2 + 2\,a^2x^3 - 4\,ax^4) - (a^5 + 4\,a^3x^2 - 3\,a^2x^3 - 4\,ax^4) =$$
$$a^3x^2 + 2\,a^2x^3 - 4\,ax^4 - a^5 - 4\,a^3x^2 + 3\,a^2x^3 + 4\,ax^4 = -a^5 - 3\,a^3x^2 + 5\,a^2x^3$$

---

* This procedure is known as "interpolation by first differences." If a more accurate result is necessary, and the accuracy of the tabulated data so warrants, "interpolation by differences of higher order" may be employed. (See Smithsonian Mathematical Tables or an advanced algebra book.)

† Electrical engineers generally use j instead of i for $\sqrt{-1}$ to avoid confusion with use of i for current.

Powers and Roots. The notation a^n denotes the nth power of a, even if the exponent n is negative or fractional. If no exponent is shown, 1 is understood. Rules for powers are: $(+a)^n = +a^n$; $(-a)^n = +a^n$ if n is an even integer and $-a^n$ if n is odd; $(a^m)^n = a^{mn}$; $a^{-n} = 1/a^n$; $a^0 = 1$; $0^a = 0$; $a^m \times a^n = a^{m+n}$; $a^m/a^n = a^{m-n}$; $(ab)^n = a^n b^n$; $\left(\frac{a}{b}\right)^n = \frac{a^n}{b^n}$.

The notation $a^{1/n}$ or $\sqrt[n]{a}$ denotes the nth root of a; n is called the index of the root. An even real root of a positive number is positive or negative, and an odd real root is positive; an odd real root of a negative number is negative, and all even roots are complex or purely imaginary. Also $a^{m/n} = \left(\sqrt[n]{a}\right)^m = \sqrt[n]{a^m}$.

Operations with radicals are performed by changing to exponents.

Example: $\sqrt{2} \times \sqrt[3]{3} = 2^{1/2} \times 3^{1/3} = 2^{3/6} \times 3^{2/6} = (2^3)^{1/6} \times (3^2)^{1/6} = 8^{1/6} \times 9^{1/6} = 72^{1/6} = \sqrt[6]{72}$.

Division by radicals may be avoided by *rationalizing*.

Example: To compute $\dfrac{\sqrt{3} + \sqrt{2}}{\sqrt{5} - \sqrt{3}}$, multiply numerator and denominator by $\sqrt{5} + \sqrt{3}$. This rationalizes the denominator, for $(\sqrt{5} - \sqrt{3})(\sqrt{5} + \sqrt{3}) = 5 - 3 = 2$, hence the value $1/2\,(\sqrt{3} + \sqrt{2})(\sqrt{5} + \sqrt{3}) = 1/2\,(3 + \sqrt{6} + \sqrt{10} + \sqrt{15})$.

The symbol i denotes $\sqrt{-1}$, which is the imaginary unit. If a is positive and n even, then $(-a)^{1/n} = a^{1/n}i$. Powers of i are $i^2 = -1$, $i^3 = -\sqrt{-1}$, $i^4 = +1$, etc. A complex quantity is the sum of a real and an imaginary quantity, as $a + ib$.

Multiplication. To find the product of monomials, multiply the product of the literal factors by the product of the numerical factors. The product is positive if all the factors are positive or if an even number of them are negative; it is negative if an odd number of them are negative.

Thus: $4a \times 3c = +12ac$; $4a \times (-3c) = -12ac$; $-4a \times (-3c) = +12ac$; $a^2 \times a^3 = a^5$; $4a^2c \times ac^3 = 4a^3c^4$; $6ab^2y^3 \times 2b^3y^3 \times (-5a^2y) = -60a^3b^6y^7$.

To multiply two polynomials, multiply each term of one factor by each term of the other factor and add the partial products.

Thus, to multiply $(-a^3 + 2a^2b - b^3)$ by $(+4a^2 + 8ab)$, the operation may be arranged and carried out thus:

$$\begin{array}{rrrrr}
-a^3 & +2a^2b & -b^3 & & \\
4a^2 & +8ab & & & \\
\hline
-4a^5 & +8a^4b & -4a^2b^3 & & \\
 & -8a^4b & & +16a^3b^2 & -8ab^4 \\
\hline
-4a^5 & & -4a^2b^3 & +16a^3b^2 & -8ab^4
\end{array}$$

If $ab = 0$, either a or b or both $= 0$.

Division. To find the quotient of monomials, multiply the quotient of the literal factors by the quotient of the numerical factors. The quotient is positive if dividend and divisor have like signs; it is negative if dividend and divisor have unlike signs.

Thus: $\dfrac{-12ac}{4a} = -3c$; $\dfrac{a^5}{a^2} = a^3$; $\dfrac{-60a^3b^6y^7}{-5a^2y} = 12ab^6y^6$.

To divide a polynomial by a polynomial, arrange both dividend and divisor according to ascending or descending powers of some common letter, and keep this order throughout the operation. Arrange the computation thus: Dividend $\left|\dfrac{\text{Divisor}}{\text{Quotient}}\right.$. Divide the first term of the dividend by the first term of the divisor and write the result as the first term of the quotient. Multiply all terms of the divisor by the first term of the quotient. Subtract the product from the dividend. If there is a remainder, consider it as a new dividend and proceed as before.

Thus: $(22a^2b^2 + 15b^4 + 3a^4 - 10a^3b - 22ab^3) \div (a^2 + 3b^2 - 2ab)$

$$\begin{array}{rrrrr|l}
3a^4 & -10a^3b & +22a^2b^2 & -22ab^3 & +15b^4 & a^2 - 2ab + 3b^2 \\
\cline{6-6}
3a^4 & -6a^3b & +9a^2b^2 & & & 3a^2 - 4ab + 5b^2 \\
\cline{1-3}
 & -4a^3b & +13a^2b^2 & -22ab^3 & & \\
 & -4a^3b & +8a^2b^2 & -12ab^3 & & \\
\cline{2-5}
 & & 5a^2b^2 & -10ab^3 & +15b^4 & \\
 & & 5a^2b^2 & -10ab^3 & +15b^4 & \\
\cline{3-5}
\end{array}$$

The quotient is $(3a^2 - 4ab + 5b^2)$.

Division by 0 is not permissible, and care must be exercised in algebraic computations that this error has not been unwittingly committed.

Useful Identities * obtained by multiplication or division include:

$(a \pm b)^2 = a^2 \pm 2\,ab + b^2$

$(a + b)(a - b) = a^2 - b^2$

$(a + b)(x + y) = ax + ay + bx + by$

$(a + b + c)^2 = a^2 + b^2 + c^2 + 2\,ab + 2\,ac + 2\,bc$

$(a^n - b^n) \div (a - b) = a^{n-1} + a^{n-2}b + a^{n-3}b^2 + \ldots + a\,b^{n-2} + b^{n-1}$ (if $a \neq b$)

$(a^n + b^n) \div (a + b) = a^{n-1} - a^{n-2}b + a^{n-3}b^2 - \ldots - a\,b^{n-2} + b^{n-1}$ (if n is odd)

$(a^n - b^n) \div (a + b) = a^{n-1} - a^{n-2}b + a^{n-2}b^2 - \ldots + a\,b^{n-2} - b^{n-1}$ (if n is even)

Factoring is the process of finding two or more expressions the product of which is equal to a given expression. The general procedure in factoring polynomials is first to factor out any monomial common to each term and then to treat the remaining polynomial by such processes as:

(1) Comparison with known identities such as those listed above.

Example: $x^2y - 4\,y^3 = y\,(x^2 - 4\,y^2) = y\,(x + 2\,y)(x - 2\,y)$.

(2) Use of the theorem: $x^2 + bx + c = (x + p)(x + q)$ if p and q are two numbers the sum of which is b and the product c.

Example: Given $x^2 - x - 6$. Since $(-3) + (2) = -1$ and $(-3) \times (2) = -6$, $p = -3$ and $q = 2$; hence $x^2 - x - 6 = (x - 3)(x + 2)$.

(3) Use of the theorem: If r is a root of $f(x) = 0$ (see p. 2–14), $(x - r)$ is a factor of $f(x)$.

Example: Given $2\,x^2 - 2\,x - 12$. By formula (p. 2–13), the roots of $2\,x^2 - 2\,x - 12 = 0$ are 3 and (-2); therefore $(x - 3)$ and $(x + 2)$ are factors and $2x^2 - 2x - 12 = 2\,(x - 3)(x + 2)$.

7. RATIONAL FRACTIONS

Fundamental Laws applying to fractions are illustrated by the following equalities:

Signs. $+\dfrac{a}{b} = \dfrac{-a}{-b} = -\dfrac{-a}{b} = -\dfrac{a}{-b}$.

Addition and Subtraction. $\dfrac{a}{c} \pm \dfrac{b}{d} = \dfrac{ad \pm bc}{cd}$; $\dfrac{a}{c} \pm \dfrac{b}{c} = \dfrac{a \pm b}{c}$; $\dfrac{a}{c} \pm \dfrac{a}{d} = \dfrac{a(d \pm c)}{cd}$. To combine several fractions, use their least common denominator. Thus:

$$\frac{a}{def} + \frac{b}{e^3g} - \frac{c}{df^2} = \frac{ae^2fg + bdf^2 - ce^3g}{de^3f^2g}.$$

Multiplication. $\dfrac{a}{b} \times \dfrac{c}{d} = \dfrac{ac}{bd}$; $\dfrac{a}{b} = \dfrac{ac}{bc}$.

Division. $\dfrac{a}{b} \div \dfrac{c}{d} = \dfrac{a}{b} \times \dfrac{d}{c} = \dfrac{ad}{bc}$; $\dfrac{a}{b} = \dfrac{a \div c}{b \div c}$.

Powers and Roots. $\dfrac{a^n}{b^n} = \left(\dfrac{a}{b}\right)^n = \left(\dfrac{b}{a}\right)^{-n} = \dfrac{b^{-n}}{a^{-n}}$ (whether n is an integer or fraction); $\left(\dfrac{a}{b}\right)^{m/n} = \left(\sqrt[n]{\dfrac{a}{b}}\right)^m = \sqrt[n]{\left(\dfrac{a}{b}\right)^m}$.

Partial Fractions

Decomposition of a Proper Fraction † into its simplest partial fractions can be accomplished by application of the following rule, where the denominator of the given fraction contains factors prime to each other (except that one or more of them may be repeated).

Rule: Set up partial fractions in accordance with the procedure given under the appropriate case (or cases) below. These partial fractions contain unknown constants. Since the equality between the given fraction and the partial fractions is an identity, the constants can be determined by equating coefficients of like powers of the variable appearing in the two members (i.e., using the method of undetermined coefficients). The latter step can sometimes be simplified by short-cut substitution methods.

---

* An *identity* is an identical equality of two expressions; that is, an equality which holds true for *all* values of the symbols.

† A *proper fraction* is one in which the numerator is of lower degree than the denominator. An *improper fraction* (for which the reverse is true) may readily be reduced, by dividing the numerator by the denominator, to give the sum of an integral part and a proper fraction.

Case I: **If the denominator can be resolved into real linear factors ($P, Q, R \ldots$), all of which are different, let** $\dfrac{\text{Num}}{PQR \ldots} = \dfrac{A}{P} + \dfrac{B}{Q} + \dfrac{C}{R} + \ldots$.

Example: $\dfrac{6x^2 - x + 1}{x^3 - x} = \dfrac{A}{x} + \dfrac{B}{x-1} + \dfrac{C}{x+1}$. **Clearing of fractions,**

$$6x^2 - x + 1 = A(x-1)(x+1) + Bx(x+1) + Cx(x-1)$$

As this equality is an identity, it is true for all values of x. Letting $x = 0$, $A = -1$; letting $x = 1$, $B = 3$; letting $x = -1$, $C = 4$. Hence, $\dfrac{6x^2 - x + 1}{x^3 - x} = -\dfrac{1}{x} + \dfrac{3}{x-1} + \dfrac{4}{x+1}$.

Or, using the method of undetermined coefficients, the identity may be written:

$$6x^2 - x + 1 = (A + B + C)x^2 + (B - C)x - A.$$

Then, $A + B + C = 6$; $B - C = -1$; $-A = 1$, and solving simultaneously, $A = -1$, $B = 3$, $C = 4$, as before.

Case II: If the denominator can be resolved into real linear factors ($P, Q \ldots$), one or more of which are repeated, let $\dfrac{\text{Num}}{P^2Q^3 \ldots} = \dfrac{A}{P} + \dfrac{B}{P^2} + \dfrac{C}{Q} + \dfrac{D}{Q^2} + \dfrac{E}{Q^3} + \ldots$

Example: $\dfrac{x+1}{x(x-1)^3} = \dfrac{A}{x} + \dfrac{B}{x-1} + \dfrac{C}{(x-1)^2} + \dfrac{D}{(x-1)^3}$. Clearing of fractions,

$$x + 1 = A(x-1)^3 + Bx(x-1)^2 + Cx(x-1) + Dx$$

Determine the constants by methods illustrated in the example under *Case I*. Constants A and D can be obtained quickly by the substitution method, but for B and C the method of undetermined coefficients should be used after simplifying the identity by substituting the numerical values of A and D, collecting terms, etc.

Case III: If the denominator contains quadratic factors ($P, Q \ldots$) which cannot be separated into real linear factors and all of which are different, let

$$\frac{\text{Num}}{PQ \ldots} = \frac{Ax + B}{P} + \frac{Cx + D}{Q} + \ldots.$$

Example: $\dfrac{3x^2 - 2}{(x^2 + x + 1)(x + 1)} = \dfrac{Ax + B}{x^2 + x + 1} + \dfrac{C}{x + 1}$. Clearing of fractions,

$$\begin{aligned} 3x^2 - 2 &= (Ax + B)(x + 1) + C(x^2 + x + 1) \\ &= (A + C)x^2 + (A + B + C)x + (B + C) \end{aligned}$$

Equate coefficients of like powers of x to determine the constants. (See example under *Case I*.)

Case IV: If the denominator contains quadratic factors ($P, Q \ldots$) which cannot be separated into real linear factors and one or more of which are repeated, let

$$\frac{\text{Num}}{P^2Q^3 \ldots} = \frac{Ax + B}{P} + \frac{Cx + D}{P^2} + \frac{Ex + F}{Q} + \frac{Gx + H}{Q^2} + \frac{Ix + J}{Q^3} + \ldots.$$

Example: $\dfrac{5x^2 - 4x + 16}{(x-3)(x^2 - x + 1)^2} = \dfrac{A}{x-3} + \dfrac{Bx + C}{x^2 - x + 1} + \dfrac{Dx + E}{(x^2 - x + 1)^2}$. Clearing of fractions,

$$5x^2 - 4x + 16 = A(x^2 - x + 1)^2 + (Bx + C)(x - 3)(x^2 - x + 1) + (Dx + E)(x - 3)$$

Proceed from here on by method similar to that discussed in example under *Case II*.

8. RATIO AND PROPORTION

Laws of Ratio and Proportion are stated in the following theorems, in which the symbols have finite values and division by zero is excluded:

(*a*) If $\dfrac{a}{b} = \dfrac{c}{d}$ then: $\dfrac{a}{c} = \dfrac{b}{d}$; $ad = bc$; $\dfrac{ma + nb}{pa + qb} = \dfrac{mc + nd}{pc + qd}$; $\left(\dfrac{a}{b}\right)^n = \left(\dfrac{c}{d}\right)^n$. If also $\dfrac{e}{f} = \dfrac{g}{h}$, then: $\dfrac{ae}{bf} = \dfrac{cg}{dh}$.

(*b*) If $\dfrac{a}{b} = \dfrac{c}{d} = \dfrac{e}{f} = \ldots$, then: $\dfrac{a}{b} = \dfrac{c}{d} = \dfrac{e}{f} = \ldots = \dfrac{pa + qc + re + \ldots}{pb + qd + rf + \ldots}$.

Variation.

If $y = kx$, y varies directly as x; i.e., y is directly proportional to x.

If $y = \dfrac{k}{x}$, y varies inversely as x; i.e., y is inversely proportional to x.

If $y = kxz$, y varies jointly as x and z.

If $y = k\dfrac{x}{z}$, y varies directly as x and inversely as z.

The symbol k is called the constant factor of proportionality.

9. INEQUALITIES

Laws of Inequalities are stated in the following theorems, in which the symbols have *finite positive values* and *division by zero* is excluded:

(*a*) If $a > b$, then: $a + c > b + c \qquad b < a$

$$a - c > b - c \qquad c - a < c - b$$

$$ac > bc \qquad -ca < -cb$$

$$\frac{a}{c} > \frac{b}{c} \qquad \frac{c}{a} < \frac{c}{b}$$

Corollary: If $a - c > b$, then $a > b + c$.

(*b*) If $a > b$ and $c > d$, then: $a + c > b + d$; $ac > bd$;
but $a - c$ may be $>$ or $=$ or $< b - d$; a/c may be $>$ or $=$ or $< b/d$.

10. LOGARITHMS

The Logarithm of a given number is the power to which a fixed number called the base must be raised to produce the given number. In $y = b^x$, b is the base, x the logarithm to this base, and y the number which is produced. For common, or Briggs, logarithms the base is 10. The only other system in frequent use is the Napierian, natural, or hyperbolic system, for which the base $e = 2.71828$ (to five decimal places). The abbreviation *log* means the logarithm of a number to the base 10. The notation ln 6 or $\log_e 6$ means the logarithm of 6 to the base e; log 6 means the logarithm of 6 to the base 10. Thus, $\log 100 = 2$, because $100 = 10^2$; $\log 10 = 1$, because $10 = 10^1$; $\log 1 = 0$, because $1 = 10^0$; $\log 0.1 = -1$, because $0.1 = 10^{-1}$. Any number > 1 has a positive logarithm, and any number < 1 has a negative logarithm (provided the base > 1). A number which is not a whole power of 10 results from raising 10 to some mixed-numbered, fractional, or irrational power. The integral part of the power is called the *characteristic* and may be either positive, zero, or negative; the decimal part, called the *mantissa*, is always positive and may be obtained from a table of logarithms. Since 10 is larger than e (2.71828), it takes a higher power of e to produce a given number than it does of 10. This means that the logarithm of a number to base e is larger than that to base 10. Relation between the two systems of logarithms is:

$$\log_e n = \log_{10} n \div \log_{10} e$$

or

$$\log_e n = \log_{10} n \div 0.4343 = \log_{10} n \times 2.303$$

Numerical Value of the *mantissa* for base 10 is taken from Table 10, Section 1, disregarding for the moment the decimal point in the number whose logarithm is being determined. The *characteristic* is determined by the following rules. If the given number is greater than 1, the characteristic of its logarithm is positive and is one less than the number of figures preceding the decimal point; thus,

$$\log 6.54 = 0.815578;\ \log 65.4 = 1.815578;\ \log 654 = 2.815578;\ \log 6540 = 3.815578$$

If the given number is less than 1, the characteristic of its logarithm is negative and is numerically one greater than the number of zeros immediately following the decimal point; thus the four-place logarithm of 6 is 0.7782, and

$$\log 0.6 = \bar{1}.7782;\ \log 0.06 = \bar{2}.7782;\ \log 0.006 = \bar{3}.7782;\ \log 0.0006 = \bar{4}.7782$$

The mantissa is always positive, so $\bar{2}.7782$ is the same as $-2 + 0.7782$ and may be written $8.7782 - 10$. If the given number is an integral power of 10, the mantissa is zero.

To determine a number whose logarithm is given, the above procedure is reversed.

The *cologarithm* of a number is the logarithm of its reciprocal. Hence, $\text{colog}\, N = \log 1/N = \log 1 - \log N = -\log N$. Cologarithms are useful (if tables of them are available) in dealing with fractions, since cologarithms of factors in the denominator may be *added* to logarithms of factors in the numerator.

Multiplication and Division of numbers may be performed by logarithms and the use of the following rules:

To multiply a by b, $\qquad \log a + \log b = \log ab$

To divide a by b, $\qquad \log a - \log b = \log a/b$

Here $\log a$ and $\log b$ are obtained from Table 10 and the above rules for the characteristic; then the number corresponding to $\log ab$ or $\log a/b$ is found from Table 10. For example, to multiply 68.31 by 0.2754, $\log 68.31 = 1.834484$, $\log 0.2754 = 9.439964 - 10$, the sum of the logs is 1.274448, and its corresponding number is 18.813, the last digit being possibly one unit in error.

Powers and Roots of numbers are most conveniently computed by logarithms and the use of the following rules:

To raise a to the nth power, $n \log a = \log a^n$
To extract the nth root of a, $\frac{1}{n} \log a = \log a^{1/n}$

For example, to raise 0.6831 to the 1.53 power: $1.53 \times \bar{1}.834484 = 1.53(-1 + .834484) = -1.53 + 1.276761 = -1 - 0.53 + 1.276761 = \bar{1}.746761$, which is log of 0.55816. To find the fifth root of 0.6831: one-fifth of $\bar{1}.834484$ is $^1/_5\,(-5 + 4.834484) = \bar{1}.966897$, which is log of 0.92661.

Simple exponential equations may be solved by a variation of the above principle. Thus, given $a^x = b$, write

$$x \log a = \log b, \text{ whence } x = \frac{\log b}{\log a} \text{ and } \log x = \log(\log b) - \log(\log a).$$

Theory of the Slide Rule

A Slide Rule is an instrument for mechanical computation based on the use of logarithms. With it the operations of multiplication, division, the finding of powers, and the extraction of roots can be performed rapidly and with an accuracy sufficient for most engineering work. With a good 10-inch Mannheim rule the results obtained are accurate to approximately $^1/_{10}$ of 1 per cent.

The Simple Mannheim Rule consists of a fixed and a sliding part both of which are ruled with logarithmic scales, i.e., with divisions at distances equal to the logarithms of the numbers marking the division points. Since the logarithm of the product of two numbers is the sum of the logarithms of the numbers and the logarithm of the quotient of two numbers is the difference of their logarithms, multiplication or division of the numbers can be effected by moving the slide to the right or left to add or subtract the logarithms. The scales on the fixed part of the rule are called the A and D scales, and those on the slide the B and C scales. The A and B scales are each divided into two parts, each part being a half-size reproduction of the C and D scale. A " runner," which consists of a glass plate with a fine vertical line on it, is used to facilitate some of the operations. Since 0 is the logarithm of 1 the numbering on each scale begins with the figure 1. In using the scale the figures 1, 2, 3, etc., are to be taken either as representing these numbers, or as 10, 20, 30, etc., or 100, 200, 300, etc., or 0.1, 0.2, 0.3, etc.; that is, the numbers multiplied or divided by 10, 100, etc., as may be most convenient for the solution of a given problem.

Use of the Simple Mannheim Slide Rule

The following examples illustrate the use of the slide rule.

Proportion. Set the first term of a proportion on the C scale opposite the second term on the D scale; then opposite the third term on the C scale read the fourth term on the D scale.

Example: Find the fourth term in the proportion 12 : 21 :: 30 : x. Move the slide to the right until 12 on C is opposite 21 on D, then opposite 30 on C read x on D, = 52.5.

Multiplication. Set 1 on the C scale opposite one of the factors on D. Under the other factor on the C scale read the product on the D scale.

Example: 25 × 3. Move the slide to the right until the left 1 on C is opposite 25 on D. Under 3 on C is found the product on D, = 75.

Example: 25 × 5. If the slide is moved to the right as above, the 5 on C will be beyond the end of D. In this case move the slide to the left until the right 1 on C is opposite 25 on D. Under 5 on C is found the product on D, = 125.

Division. Place the divisor on C opposite the dividend on D, and the quotient is found on D under 1 on C.

Example: 750 ÷ 25. Move the slide until 25 on C is opposite 750 on D. Under 1 on C is found the quotient on D, = 30.

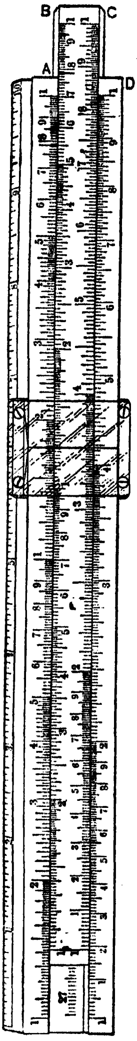

Fig. 1

Combined Multiplication and Division. Arrange the numbers to be multiplied and divided in the form of a fraction with one more factor in the numerator than in the denominator, supplying the factor 1 if necessary. Then perform alternate division and multiplication, using the runner to indicate partial results.

Example: $\frac{4 \times 5 \times 8}{3 \times 6} = 8.9$ nearly. Set 3 on C over 4 on D, set runner to 5 on C, then set 6 on C under the runner, and read under 8 on C the result 8.9 – on D.

Powers and Roots. The numbers on scales A and B are the squares of the opposite numbers on scales C and D, and the numbers on scales C and D the square roots of the opposite numbers on scales A and B. In extracting square roots, if the number of digits is odd, take the number on the left-hand scale of A; if the number of digits is even, take the number on the right-hand scale of A. To cube a number, perform the operations of squaring and multiplication.

Examples: $4^2 = 16$. Set the runner over 4 on D and read 16 on A. $\sqrt{16} = 4$. Set the runner over 16 on A and read 4 on D. $2^3 = 8$. Set 1 on C over 2 on D, and above 2 on B read the result 8 on A.

Cube Root. Set the runner over the number on A; then move the slide until there is found under the runner on B the same number which is found under 1 on C on D; this number is the cube root desired.

Example: $\sqrt[3]{8} = 2$. Set the runner over 8 on A, move the slide along until the same number appears under the runner on B and under 1 on C on D; this is the number 2.

Trigonometric Computations. On the under side of the slide (which is reversible) are three scales, a scale of natural sines marked S, a scale of natural tangents marked T, and between these a scale of equal parts. To use these scales, turn the slide over. Opposite an angle on S its sine is found on A, and opposite an angle on T is found its tangent on D.

To solve a right triangle in which the two arms are given, use the T and D scales. Set the end of the T scale opposite the longer arm on D and find the smaller angle on T opposite the shorter arm on D. In all other cases use the A and S scales. Set a given side on A opposite its opposite angle on S. With this setting the hypotenuse is opposite 90°, the longer arm opposite the larger acute angle, and the shorter arm opposite the smaller acute angle.

Example: Given, shorter arm = 24, opposite angle = 35.5°. Find the remaining parts of the triangle.

Set 35.5° on S opposite 24 on A. Opposite 54.5° on S read the longer arm 33.6 on A and opposite 90° on S the hypotenuse 41.3 on A.

Vector Computations. Scales for circular and hyperbolic functions have been designed by M. P. Weinbach and A. F. Puchstein to facilitate computations involving these functions and complex numbers. For detailed instructions in their use consult the manual of The Log Log Vector Slide Rule published by Keuffel and Esser Co.

11. EQUATIONS

An Equation is a statement of conditional equality between two expressions. Algebraic equations contain one or more letter symbols representing *unknown* quantities. The process of determining values of unknowns satisfying the equations is called *solving the equations.* The solutions of an equation in one unknown are called its *roots.*

The following theorem is of fundamental importance: If the same quantity is added to, or subtracted from, both sides (i.e., *members*) of an equation, or if both members are multiplied or divided by the same quantity (excluding division by zero), the equality is not disturbed. It follows that any term may be *transposed* from one side of an equation to the other provided its sign is changed.

A Linear Equation is an equation of the first degree; that is, one in which, after clearing of fractions, only terms of the first degree in the variable (or variables) appear. A linear equation in one unknown has only one root. Example: Given, $3x + 2 = 0$. Solution: $x = -\,^2/_3$.

Quadratic Equation

A Quadratic Equation is an equation of the second degree; that is, one in which, after clearing of fractions, one or more terms of the second degree (as x^2 or xy) in the variable (or variables) appear, but none of higher degree. A quadratic equation in one unknown has two roots which are either both real or both complex. The roots may be determined by any one of the following methods:

Solution by Factoring. Given the equation $ax^2 + bx + c = 0$ (abbreviated $f(x) = 0$). If $(x - r)$ is a factor of $f(x)$, then r is a root of $f(x) = 0$. Factors can sometimes be written by inspection. (See p. 2–14.) Example: Given: $x^2 - x - 6 = 0$. This may be written $(x - 3)(x + 2) = 0$. Hence, the roots are 3 and -2.

Solution by Completing the Square. The equation $ax^2 + bx + c = 0$ may be written in the form $x^2 + \frac{b}{a}x = -\frac{c}{a}$. Add $\left(\frac{b}{2a}\right)^2$ to both members. Then

$$x^2 + \frac{b}{a}x + \left(\frac{b}{2a}\right)^2 = -\frac{c}{a} + \left(\frac{b}{2a}\right)^2 \quad \text{or} \quad \left(x + \frac{b}{2a}\right)^2 = \frac{b^2 - 4ac}{4a^2}$$

$$\text{whence} \quad \left(x + \frac{b}{2a}\right) = \pm\frac{\sqrt{b^2 - 4ac}}{2a} \quad \text{or} \quad x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} = \text{the roots}$$

Example: Given, $2x^2 + x - 3 = 0$. This may be written $x^2 + 1/2\,x = 3/2$. Add $(1/4)^2$ to both members. Then $x^2 + 1/2\,x + (1/4)^2 = 3/2 + (1/4)^2$, or $(x + 1/4)^2 = 25/16$, whence $(x + 1/4) = \pm 5/4$ and $x = 1$ or $-3/2$ = the roots.

Solution by Formula. The symbolic solution of $ax^2 + bx + c = 0$ is

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a},$$

as shown above. This solution may be used as a general formula. Thus, in the previous example of $2x^2 + x - 3 = 0$, the coefficients are $a = 2$, $b = 1$, $c = -3$. Substituting these values into the formula, $x = \frac{-1 \pm \sqrt{(1)^2 - 4(2)(-3)}}{2 \times 2} = \frac{-1 \pm 5}{4} = 1$ or $-\frac{3}{2}$, as before.

The Discriminant of the equation $ax^2 + bx + c = 0$ is the quantity $b^2 - 4ac$. If $b^2 - 4ac > 0$, the roots are real and unequal; if $b^2 - 4ac = 0$, the roots are real and equal; if $b^2 - 4ac < 0$, the roots are complex and unequal. If $b^2 - 4ac$ is a positive perfect square, or zero, the roots are rational. If $b = 0$, the roots are equal in absolute value but opposite in sign; if $c = 0$, one root is zero.

Cubic Equation

A Cubic Equation is an equation of the third degree; that is, one in which, after clearing of fractions, one or more terms of the third degree in the variable (or variables) appear, but none of higher degree. A cubic equation in one unknown has three roots, of which either all are real or one real and two complex.

Algebraic Solution. Write the equation in the form $ax^3 + 3bx^2 + 3cx + d = 0$. Let

$$q = ac - b^2 \quad \text{and} \quad r = 1/2\,(3abc - a^2d) - b^3.$$

Also let $$s_1 = \left(r + \sqrt{q^3 + r^2}\right)^{1/3} \quad \text{and} \quad s_2 = \left(r - \sqrt{q^3 + r^2}\right)^{1/3}.$$

Then the roots are:

$$x_1 = [(s_1 + s_2) - b] \div a$$

$$x_2 = \left[-\frac{1}{2}(s_1 + s_2) + \frac{\sqrt{-3}}{2}(s_1 - s_2) - b\right] \div a$$

$$x_3 = \left[-\frac{1}{2}(s_1 + s_2) - \frac{\sqrt{-3}}{2}(s_1 - s_2) - b\right] \div a$$

If $q^3 + r^2 > 0$, there are one real root and a pair of complex roots. If $q^3 + r^2 = 0$, all three roots are real and at least two are equal. If $q^3 + r^2 < 0$, all three roots are real but the numerical solution leads to the extraction of the cube roots of complex quantities, and therefore the algebraic forms are *irreducible*. In such a case the trigonometric solution should be employed.

Example: Given the equation $x^3 + 12x^2 + 45x + 54 = 0$.
Here $a = 1$, $b = 4$, $c = 15$, $d = 54$. $q = 15 - 16 = -1$; $r = 1/2\,(180 - 54) - 64 = -1$; $q^3 + r^2 = -1 + 1 = 0$, $s_1 = s_2 = (-1)^{1/3} = -1$. $s_1 + s_2 = -2$; $s_1 - s_2 = 0$.
Hence the roots are $x_1 = (-2 - 4) = -6$; $x_2 = x_3 = [-1/2\,(-2) - 4] = -3$.

Trigonometric Solution. Write the equation in the form $ax^3 + 3bx^2 + 3cx + d = 0$. Let $q = ac - b^2$ and $r = 1/2\,(3abc - a^2d) - b^3$ (as in algebraic solution). Then the roots are:

$$x_1 = (y_1 - b) \div a$$

$$x_2 = (y_2 - b) \div a$$

$$x_3 = (y_3 - b) \div a$$

where y_1, y_2, and y_3 have the following values (upper of alternative signs being used when r is $+$ and the lower when r is $-$):

Case I: If q is $-$ and $q^3 + r^2 \leqq 0$:

$$y_1 = \pm 2\sqrt{-q}\cos\left[\frac{1}{3}\cos^{-1}\frac{\pm r}{\sqrt{-q^3}}\right]$$

$$y_2 = \pm 2\sqrt{-q}\cos\left[\frac{1}{3}\cos^{-1}\frac{\pm r}{\sqrt{-q^3}} + \frac{2\pi}{3}\right]$$

$$y_3 = \pm 2\sqrt{-q}\cos\left[\frac{1}{3}\cos^{-1}\frac{\pm r}{\sqrt{-q^3}} + \frac{4\pi}{3}\right]$$

Case II: If q is $-$ and $q^3 + r^2 \geqq 0$:

$$y_1 = \pm 2\sqrt{-q}\cosh\left[\frac{1}{3}\cosh^{-1}\frac{\pm r}{\sqrt{-q^3}}\right]$$

$$y_2 = \mp\sqrt{-q}\cosh\left[\frac{1}{3}\cosh^{-1}\frac{\pm r}{\sqrt{-q^3}}\right] + i\sqrt{-3q}\sinh\left[\frac{1}{3}\cosh^{-1}\frac{\pm r}{\sqrt{-q^3}}\right]$$

$$y_3 = \mp\sqrt{-q}\cosh\left[\frac{1}{3}\cosh^{-1}\frac{\pm r}{\sqrt{-q^3}}\right] - i\sqrt{-3q}\sinh\left[\frac{1}{3}\cosh^{-1}\frac{\pm r}{\sqrt{-q^3}}\right]$$

Case III: If q is $+$:

$$y_1 = \pm 2\sqrt{q}\sinh\left[\frac{1}{3}\sinh^{-1}\frac{\pm r}{\sqrt{q^3}}\right]$$

$$y_2 = \mp\sqrt{q}\sinh\left[\frac{1}{3}\sinh^{-1}\frac{\pm r}{\sqrt{q^3}}\right] + i\sqrt{3q}\cosh\left[\frac{1}{3}\sinh^{-1}\frac{\pm r}{\sqrt{q^3}}\right]$$

$$y_3 = \mp\sqrt{q}\sinh\left[\frac{1}{3}\sinh^{-1}\frac{\pm r}{\sqrt{q^3}}\right] - i\sqrt{3q}\cosh\left[\frac{1}{3}\sinh^{-1}\frac{\pm r}{\sqrt{q^3}}\right]$$

Example: Given the equation $x^3 + 6x^2 - 9x - 54 = 0$.

Here $a = 1$, $b = 2$, $c = -3$, $d = -54$; $q = -3 - 4 = -7$; $r = 1/2(-18 + 54) - 8 = 10$; $q^3 + r^2 = -343 + 100 = -243$. Note that q is $-$; $q^3 + r^2 < 0$; r is $+$.

Therefore use *Case I* with upper signs.

$$y_1 = 2\sqrt{7}\cos\left[\frac{1}{3}\cos^{-1}\frac{10}{\sqrt{343}}\right] = 2\sqrt{7}\cos 19.1° = 5$$

Hence, one root is $x_1 = 5 - 2 = 3$. The other roots can be similarly determined.

Biquadratic Equation

Method of Solution. Given the equation $x^4 + ax^3 + bx^2 + cx + d = 0$. First find any real root y_1 of the cubic equation:

$$8y^3 - 4by^2 + 2(ac - 4d)y - [c^2 + d(a^2 - 4b)] = 0$$

Then the four roots of the biquadratic equation are given by the roots of the following two quadratic equations:

$$x^2 + \left[\frac{a}{2} - \sqrt{\frac{a^2}{4} + 2y_1 - b}\right]x + \left(y_1 + \sqrt{y_1^2 - d}\right) = 0$$

$$x^2 + \left[\frac{a}{2} + \sqrt{\frac{a^2}{4} + 2y_1 - b}\right]x + \left(y_1 - \sqrt{y_1^2 - d}\right) = 0$$

*N*th Degree Equation

Fundamental Theorems of importance in the solution of nth degree equations in one unknown are given below. $f(x)$ represents an nth degree polynomial written in descending integral powers of x with all terms considered present even though some may have zero coefficients.

Theorem I: If $f(x)$ is divided by $(x - r)$, the remainder is the value of $f(x)$ resulting if r is substituted for x, which value is designated by $f(r)$. This is known as the *remainder theorem*.

Theorem II: If, and only if, $f(x)$ is exactly divisible by $(x - r)$, will r be a root of $f(x) = 0$. An nth degree equation has n such factors and consequently n roots.

Theorem III: In the equation $f(x) = 0$, if the coefficient of the first term is unity, then the coefficient of the second term with sign changed equals the sum of all the roots; the coefficient of the third term equals the sum of all products formed from two of the roots at a time; the coefficient of the fourth term with sign changed equals the sum of all the products formed from three of the roots at a time; etc. If the degree is even, the last coefficient equals the product of all roots; if odd, the last coefficient, with sign changed, equals the product of all roots.

***Theorem IV*: In the equation $f(x) = 0$, if all coefficients are integral, every integral root is a factor of the last term of $f(x)$.**

***Theorem V*: In the equation $f(x) = 0$, if the coefficient of the first term is unity, and the other coefficients are integral, there cannot be a fractional† root.**

***Theorem VI*: In the equation $f(x) = 0$, if x is replaced by y/m, the roots of the resulting equation $\phi(y) = 0$ are m times corresponding roots of $f(x) = 0$.**

***Theorem VII*: In the equation $f(x) = 0$, if x is replaced by $(-y)$, the roots of the resulting equation $\phi(y) = 0$ are equal in absolute value but opposite in sign to corresponding roots of $f(x) = 0$.**

***Theorem VIII*: In the equation $f(x) = 0$, if x is replaced by $(y + h)$, the roots of the resulting equation $\phi(y) = 0$ are less by h than corresponding roots of $f(x) = 0$.**

***Theorem IX*: If two consecutive coefficients of $f(x)$ have unlike signs, a *variation of sign* is said to occur. In the equation $f(x) = 0$, the number of positive roots cannot exceed the number of variations of sign of $f(x)$, and the number of negative roots cannot exceed the number of variations of sign of $f(-x)$. This is known as *Decartes' rule of signs*.**

Theorem X*: In the equation $f(x) = 0$, if two real numbers a and b, when substituted for x, give numerical values for $f(x)$ [designated $f(a)$ and $f(b)$] differing in sign, then an odd number of roots lie between $x = a$ and $x = b$. This is known as the *location theorem*.

Synthetic Division is a useful aid in the application of certain of the above theorems. To divide $f(x)$ by $(x - r)$, proceed as illustrated by the following example:

To divide $3x^3 + 4x^2 - 6x + 5$ by $(x - 2)$: The number 2 ($= r$) is bracketed to the right of the line of coefficients. The first coefficient 3 is written down below the original ones. Multiply it by 2 and add the product ($3 \times 2 = 6$) to the second coefficient 4. Multiply the sum ($4 + 6 = 10$) by 2, and add the product ($10 \times 2 = 20$) to the third coefficient -6. Continuing, the last sum 33 is the remainder, and the preceding sums, 3, 10, and 14, are successive coefficients of the quotient $3x^2 + 10x + 14$.

$$\text{Solution: } \begin{array}{rrrr|l} 3 + & 4 - & 6 + & 5 & 2 \\ & + 6 + & 20 + & 28 & \\ \hline \underbrace{3 + 10 + 14}_{} & & & + 33 = \text{Remainder} & \end{array}$$

Coefficients of quotient, $3x^2 + 10x + 14$.

If powers of x are missing in the given polynomial, their places are to be supplied by zero coefficients.

Imaginary Roots. If the coefficients in the equation $f(x) = 0$ are real, then any imaginary roots occur only in conjugate pairs of the general form $(a + bi)$ and $(a - bi)$, where $i = \sqrt{-1}$. Existence of imaginary roots may often be established by *Theorem IX*, since if the total possible number of positive and negative roots does not equal the degree of the equation, the difference (plus 1 if it is odd) represents the *minimum* number of imaginary roots.

Integral Roots. The method of determining integral roots is illustrated by example. To find the roots of $x^4 - x^3 - 9x^2 + 11x + 6 = 0$. From *Theorem IV*, possible integral roots are ± 1, ± 2, ± 3, ± 6. From *Theorem V*, there can be no fractional roots. From *Theorem IX*, there can be not more than two positive roots and not more than two negative roots (but there need not be that many of either). Whether or not there are irrational or imaginary roots is not yet known.

Try $+1$ and -1 as roots by direct substitution. Neither is a root. Applying *Theorem II*, try $+2$ as a root, using synthetic division. It is found to be a root. The equation now may be written $(x - 2)(x^3 + x^2 - 7x - 3) = 0$.

$$\begin{array}{rrrrr|l} 1 - & 1 - & 9 + & 11 + & 6 & 2 \\ & + 2 + & 2 - & 14 - & 6 & \\ \hline 1 + & 1 - & 7 - & 3 & 0 & \end{array}$$

The second factor shows that only $+3$ or -3 need be tried. Try -3. It is a root. Equation now is $(x - 2)(x + 3)(x^2 - 2x - 1) = 0$. Solving for roots of the quadratic factor by formula (p. 2–13), they are found to be $1 \pm \sqrt{2}$. Hence the roots of the given equation are $2, -3, 1 + \sqrt{2}, 1 - \sqrt{2}$.

$$\begin{array}{rrrr|l} 1 + & 1 - & 7 - & 3 & -3 \\ & - 3 + & 6 + & 3 & \\ \hline 1 - & 2 - & 1 & 0 & \end{array}$$

Fractional Roots. The method of determining fractional roots is illustrated by example. To find the roots of $36x^4 - 55x^2 - 35x - 6 = 0$. From *Theorem IV*, possible integral roots are ± 1, ± 2, ± 3, ± 6. *Theorem V* shows that fractional roots may exist. From *Theorem IX*, there can be not more than one positive and not more than three negative roots (but there need not be that many of either). Whether or not there are irrational or imaginary roots is not yet known.

Employing the method for determining integral roots, none is found. To check for fractional roots, the given equation should be replaced by one satisfying the conditions of *Theorem V* (and therefore having no fractional roots) by employing *Theorem VI*. Divide the members of the given equation by 36 (the coefficient of x^4); then let $x = y/m$ throughout; and finally multiply both members of this new equation by m^4 (which procedure does not affect the values of its roots). The last two steps may be performed more quickly by simply replacing x by y and multiplying the second term by m; the third term by m^2; etc. (assuming no terms missing). This gives $y^4 - {}^{55}/_{36}\, m^2y^2 - {}^{35}/_{36}\, m^3y - {}^{1}/_{6}\, m^4 = 0$. Now let m equal the smallest number which will clear of fractions; this is 6. The result is $y^4 - 55\,y^2 - 210\,y - 216 = 0$. This equation is found to have the integral roots -2, -3, -4, 9. Hence, by *Theorem VI*, the roots of the original equation are $-{}^1/_3$, $-{}^1/_2$, $-{}^2/_3$ and ${}^3/_2$.

---

* *Sturm's theorem* gives a method for determining the exact number of real roots lying between a and b. (See any advanced algebra book.)

† In this section *fractional* means *rational fractional*.

Irrational Roots. A method of determining positive irrational roots, known as *Horner's method*,* is illustrated by example. To find the real roots of $x^4 - 2\,x^3 + 4\,x^2 - 15\,x + 14 = 0$. First depress the equation by removing any rational roots. By a method previously discussed, $+2$ is found to be the only integral root. The depressed equation (using synthetic division) becomes $x^3 + 4\,x - 7 = 0$. This has no integral roots, and by *Theorem V* it has no fractional roots. From *Theorem IX*, there can be not more than one positive root and no negative roots. Therefore there must be a pair of imaginary roots. By the above process of elimination, the remaining root must be irrational.

By direct substitution, or by synthetic division (noting *Theorem I*), or by plotting $f(x) = x^3 + 4\,x - 7$ (see *Graphical Solution*, below), $f(x)$ is found to change sign between $+1$ and $+2$. Therefore, by *Theorem X*, the irrational root lies between these two values. Using *Theorem VIII*, let $x = y + 1$ in order to diminish the irrational root of $f(x) = 0$ by 1, thus making the corresponding root of $\phi(y) = 0$ lie between 0 and 1. This is very easily accomplished by synthetic division by dividing $f(x)$ by $(x - 1)$; then dividing the new quotient by $(x - 1)$; etc., the remainders furnishing coefficients of the transformed equation.† The numerical work is illustrated at the right.

The first transformed equation becomes $\phi(y) = y^3 + 3\,y^2 + 7\,y - 2 = 0$ and has a root between 0 and 1. By plotting $\phi(y)$ to large scale, the root is found to lie between 0.2 and 0.3. Therefore the corresponding root of the original equation lies between 1.2 and 1.3.

$$\begin{array}{llll|l}
1 & +\,0 & +\,4 & -\,7 & \underline{1} \\
 & +\,1 & +\,1 & +\,5 & \\ \hline
1 & +\,1 & +\,5 & -\,2 & \\
 & +\,1 & +\,2 & & \\ \hline
1 & +\,2 & +\,7 & & \\
 & +\,1 & & & \\ \hline
1 & +\,3 & & &
\end{array}$$

Next diminish the irrational root of $\phi(y) = 0$ by 0.2 to obtain an equation with roots between 0 and 0.1. The second transformed equation becomes $\psi(z) = z^3 + 3.6\,z^2 + 8.32\,z - 0.472 = 0$ and has a root between 0 and 0.1. By plotting (or more simply, by neglecting higher powers of z and putting $8.32\,z = 0.472$),‡ it is found to lie between 0.05 and 0.06. Therefore the corresponding root of the original equation lies between 1.25 and 1.26. Continuing in like manner, the irrational root may be found to any required number of decimal places.

$$\begin{array}{llll|l}
1 & +\,3 & +\,7 & -\,2 & \underline{0.2} \\
 & +\,0.2 & +\,0.64 & +\,1.528 & \\ \hline
1 & +\,3.2 & +\,7.64 & -\,0.472 & \\
 & +\,0.2 & +\,0.68 & & \\ \hline
1 & +\,3.4 & +\,8.32 & & \\
 & +\,0.2 & & & \\ \hline
1 & +\,3.6 & & &
\end{array}$$

Negative Irrational Roots of $f(x) = 0$ are obtained by replacing x by $(-y)$; finding corresponding positive irrational roots of the transformed equation $\phi(y) = 0$; and then, by *Theorem VII*, changing the signs of the roots thus determined.

Graphical Solution is frequently employed when the degree of an equation is higher than 2, or only approximate values of the roots are required, or fractional or irrational exponents appear, or transcendental functions are involved. Assume the given equation to be $f(x) = 0$. Plot the graph of $y = f(x)$; then the abscissas of the intersections of the graph with the x axis are roots of $f(x) = 0$. Or break up $f(x)$ into the difference of two functions of x as $f_1(x)$ and $f_2(x)$, and plot the graphs of $y = f_1(x)$ and $y = f_2(x)$; then the abscissas of the intersections of the two graphs are roots of $f(x) = 0$.

12. DETERMINANTS

A Determinant of the nth order is a square array of n^2 elements represented by

$$\Delta = \begin{vmatrix} a_1 & b_1 & c_1 & \ldots & l_1 \\ a_2 & b_2 & c_2 & \ldots & l_2 \\ a_3 & b_3 & c_3 & \ldots & l_3 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ a_n & b_n & c_n & \ldots & l_n \end{vmatrix}$$

and having a value determined by its *expansion* (or *development*) into $n!$ *terms* forming the algebraic sum of all the different products obtainable by using as factors one and only one *element* from each column and each row of the array, with sign affixed to each term (or product) in accordance with a general rule given below. The *principal diagonal* consists of the elements $a_1\, b_2\, c_3 \ldots l_n$.

---

* Other approximation methods known as Newton's method and Graeffe's method can be found in advanced algebra books.

† For proof of the theorem upon which this procedure is based, see any advanced algebra book.

‡ Caution must be used with this short-cut method. In this connection, an error may sometimes be caught later by noting that after a single root has been isolated between two limits, the first remainder after each synthetic division (which represents the last term in the new transformed equation) must never change sign. This fact follows from graphical considerations.

Evaluation of Determinants

Simple Cases. **A second order determinant** is expanded thus:

$\Delta = \begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} = a_1 b_2 - a_2 b_1$. In the case of a **third order determinant, the first and** second columns are rewritten, for convenience, to the right of the determinant; then the diagonals running down from left to right give the positive terms and those running up from left to right give the negative terms. (*Caution: This method cannot be applied to higher order determinants.*) Thus:

$$\Delta = \left|\begin{matrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{matrix}\right| \begin{matrix} a_1 & b_1 \\ a_2 & b_2 \\ a_3 & b_3 \end{matrix} = \left\{ \begin{matrix} a_1 b_2 c_3 + b_1 c_2 a_3 + c_1 a_2 b_3 \\ -a_3 b_2 c_1 - b_3 c_2 a_1 - c_3 a_2 b_1 \end{matrix} \right\}$$

General Case. The *first minor* of any element, as c_k, is the determinant formed of the elements remaining after suppressing the column and row to which c_k belongs; it may be designated C_k. Any determinant may be expressed in terms of the elements of a column (or row) and their first minors as follows:

Rule: Form the product of each element in a column (or row) by its corresponding minor. Give each product thus formed a positive or a negative sign according as the sum of the number of the column and the number of the row containing the element is even or odd. Keep repeating the process on the determinants formed by the minors until determinants can be expanded easily. The algebraic sum of the final resulting terms is the value of the determinant.

$$\text{Thus,} \quad \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = a_1 \begin{vmatrix} b_2 & c_2 \\ b_3 & c_3 \end{vmatrix} - a_2 \begin{vmatrix} b_1 & c_1 \\ b_3 & c_3 \end{vmatrix} + a_3 \begin{vmatrix} b_1 & c_1 \\ b_2 & c_2 \end{vmatrix}$$

$$= a_1 (b_2 c_3 - b_3 c_2) - a_2 (b_1 c_3 - b_3 c_1) + a_3 (b_1 c_2 - b_2 c_1).$$

Properties of Determinants

Simplification of the work involved in evaluating a determinant may often be accomplished by consideration of certain general properties of determinants. The most important of these are given by the following theorems:

Theorem I: A determinant vanishes if:

(*a*) It has two identical rows (or columns).

(*b*) Corresponding elements of two rows (or columns) have a constant ratio.

(*c*) The ratio of the differences of corresponding elements in one pair of rows (or columns) to the differences of corresponding elements in a second pair of rows (or columns) is constant.

Theorem II: A determinant is not changed in value by:

(*a*) Interchanging all corresponding rows and columns.

(*b*) Adding to each element of a row (or column) the corresponding element of another row (or column) multiplied by a constant factor.

Theorem III: A determinant is not changed in absolute value but is changed in sign if two rows (or columns) are interchanged.

Theorem IV: A determinant having the sum of two or more terms appearing in each element of a given row (or column) is equal to the sum of two or more determinants having for elements of that row (or column), the separate terms of that row (or column) of the given determinant.

Theorem V: A determinant is multiplied by a given factor if each element of a row (or column) is multiplied by the same factor.

Example:

$$\Delta = \begin{vmatrix} 2 & 9 & 9 & 4 \\ 2 & -3 & 12 & 8 \\ 4 & 8 & 3 & -5 \\ 1 & 2 & 6 & 4 \end{vmatrix} = \underset{\text{(Theorem II}b\text{)}}{\begin{vmatrix} 2 & 5 & 9 & 4 \\ 2 & -7 & 12 & 8 \\ 4 & 0 & 3 & -5 \\ 1 & 0 & 6 & 4 \end{vmatrix}} = 3 \underset{\text{(Theorem V)}}{\begin{vmatrix} 2 & 5 & 3 & 4 \\ 2 & -7 & 4 & 8 \\ 4 & 0 & 1 & -5 \\ 1 & 0 & 2 & 4 \end{vmatrix}}$$

$$= \underset{\text{(Expanding)}}{3 \times (-5) \begin{vmatrix} 2 & 4 & 8 \\ 4 & 1 & -5 \\ 1 & 2 & 4 \end{vmatrix} + 3 \times (-7) \begin{vmatrix} 2 & 3 & 4 \\ 4 & 1 & -5 \\ 1 & 2 & 4 \end{vmatrix}} = \underset{\text{(Theorem I}b\text{)}}{0} \; - 21 \underset{\text{(Theorem II}b\text{)}}{\begin{vmatrix} 1 & 1 & 0 \\ 4 & 1 & -5 \\ 1 & 2 & 4 \end{vmatrix}}$$

$$= \underset{\text{(Expanding)}}{-21 \begin{vmatrix} 1 & -5 \\ 2 & 4 \end{vmatrix} - (-21) \begin{vmatrix} 4 & -5 \\ 1 & 4 \end{vmatrix}} = \underset{\text{(Expanding)}}{-21 \left[(4 + 10) - (16 + 5) \right]} = +147$$

13. SYSTEMS OF LINEAR EQUATIONS

General Considerations

Two linear equations in two unknowns are **independent** if they express *different* relations between the unknowns; otherwise, they are **dependent**. The equations are **compati-**

ble if there is at least one set of values of the unknowns which satisfies both equations; otherwise, the equations are **incompatible** (or **inconsistent**). They are called **simultaneous equations** if the letter symbols are considered as representing values which satisfy both equations. **Solving** the equations simultaneously consists of finding these values. The two equations considered together form a **system** of equations.

Similar definitions apply if the system contains more than two equations and any number of unknowns. Not all the unknowns need appear in any one equation. A system of linear equations containing the same number of unknowns as independent equations gives one and only one set of values which satisfy all the equations simultaneously, that is, one solution. A system containing more unknowns than independent equations has an infinite number of solutions. A system containing fewer unknowns than independent equations has no solution as it is incompatible.

An equation is **homogeneous** if all its terms are of the same degree in the variables; otherwise, it is **non-homogeneous.** It follows that a homogeneous equation can contain no constant term (other than zero).

Methods of Solution

Two or Three Independent Linear Equations in as many unknowns can usually be solved simultaneously most quickly by a process of *elimination of unknowns.* Distinction is sometimes made between elimination by *addition and/or subtraction,* by *substitution,* and by *comparison,* but basically all three methods are closely related. The following example illustrates elimination by addition and subtraction:

$$\text{Solve:} \quad \begin{cases} 2x + y + 3z = 9 & (1) \\ x - 2y + z = -2 & (2) \\ 3x + 2y + 2z = 7 & (3) \end{cases}$$

$$\begin{aligned} (2) + (3) \text{ gives:} \quad & 4x + 3z = 5 && (4) \\ 2 \times (1) + (2) \text{ gives:} \quad & 5x + 7z = 16 && (5) \\ 5 \times (4) - 4 \times (5) \text{ gives:} \quad & -13z = -39 \text{ or } z = 3 \end{aligned}$$

Putting $z = 3$ in (4) or (5): $x = -1$
Then from (1), (2), or (3): $y = 2$

Any Number of Independent Linear Equations in an equal number of unknowns can be solved simultaneously by the above process, but if more than three *non-homogeneous* equations are involved, the computations can usually be greatly facilitated by the aid of determinants. (To condense the explanation, however, a system of only three equations will be used.)

Consider the equations:

$$\begin{aligned} 2x + y + 3z &= 9 \\ x - 2y + z &= -2 \\ 3x + 2y + 2z &= 7 \end{aligned}$$

(Note that all constants are placed in the right-hand members.)

The determinant of the coefficients, $\Delta = \begin{vmatrix} 2 & 1 & 3 \\ 1 & -2 & 1 \\ 3 & 2 & 2 \end{vmatrix}$ is called the *determinant of the system.*

Rule: Any unknown is equal to a fraction whose denominator is the determinant of the system and whose numerator is the same determinant except for replacement of each coefficient of the unknown sought by the constant term in the same equation.

Thus in the above example:

$$x = \frac{\begin{vmatrix} 9 & 1 & 3 \\ -2 & -2 & 1 \\ 7 & 2 & 2 \end{vmatrix}}{\begin{vmatrix} 2 & 1 & 3 \\ 1 & -2 & 1 \\ 3 & 2 & 2 \end{vmatrix}} = \frac{\begin{vmatrix} 9 & 1 & 3 \\ -2 & -2 & 1 \\ 5 & 0 & 3 \end{vmatrix}}{\begin{vmatrix} 2 & 1 & 3 \\ 1 & -2 & 1 \\ 4 & 0 & 3 \end{vmatrix}} = \frac{\begin{vmatrix} 9 & 1 & 3 \\ 16 & 0 & 7 \\ 5 & 0 & 3 \end{vmatrix}}{\begin{vmatrix} 2 & 1 & 3 \\ 5 & 0 & 7 \\ 4 & 0 & 3 \end{vmatrix}} = \frac{-(48 - 35)}{-(15 - 28)} = -1$$

If there are n non-homogeneous linear equations in $(n - 1)$ unknowns, and any one equation is not independent of the rest, there are in effect $(n - 1)$ independent equations in $(n - 1)$ unknowns, and the determinant of the coefficients (with the constant terms used for the last column) must equal zero.

Any number of independent *homogeneous* linear equations in an equal number of unknowns has the single solution consisting of zero values for all unknowns. However, if not all the equations are independent, there is an infinite number of solutions and the determinant of the system must equal zero.

14. SPECIAL SYSTEMS OF *N*TH DEGREE EQUATIONS

Two Quadratic Equations, or one quadratic and one linear equation, in two unknowns, can be solved by a process of elimination. Obtain a third equation containing only one of the unknowns; solve it; then substitute in the given linear equation, or one of the given quadratic equations, to obtain corresponding values of the other unknown. Numerous special methods which facilitate the work of solving in certain cases are discussed in standard algebra books. Fundamentally, however, all of them are based on a process of elimination of one variable.

A pair of quadratic equations has four sets of values (including imaginary solutions) which satisfy them simultaneously; a quadratic equation and a linear equation have two simultaneous solutions.

A Graphical Method of solution applicable to simultaneous equations *of any degree in two unknowns* is of particular value if the equations are not linear. (See page 2–16).

15. SPECIAL SERIES

A Series is an expression indicating the summation of a sequence of terms. If a series ends with some particular term, it is a *finite series*; but if the terms are formed according to some fixed law and their number is infinite, the result is an *infinite series*. A *convergent series* is one in which, if the number of terms is indefinitely increased, the sum approaches some finite value as a limit; a *divergent series* is one whose sum, thus taken, increases indefinitely or oscillates. Many series are convergent for values of the variable lying within a certain range (or ranges) and divergent for values in another range (or ranges).

Binomial Theorem

The Binomial Theorem gives a method of writing a power of a binomial as a series. It is:

$$(a \pm b)^n = a^n \pm na^{n-1}b + \frac{n(n-1)}{2!}a^{n-2}b^2 \pm \frac{n(n-1)(n-2)}{3!}a^{n-3}b^3 + \ldots$$
$$(\pm 1)^{r-1}\frac{n(n-1)\ldots(n-r+2)}{(r-1)!}a^{n-r+1}b^{r-1}\ldots$$

where the last term shown is the rth term.

If n is a positive integer, the series is finite; it has $(n+1)$ terms, the last being b^n; and the equality is true for all finite values of a and b. However, if n is fractional or negative, the series is infinite; it is convergent only for $|b| < |a|$ (see p. 2–80); and therefore the equality is true only for values of a and b thus related.

The coefficients n, $\frac{n(n-1)}{2!}$, . . . are called *binomial coefficients*. For convenience, the symbol $\binom{n}{r}$ is frequently used to represent the quantity $\frac{n(n-1)\ldots(n-r+1)}{r!}$. This is the coefficient of the $(r+1)$th term. Thus $\binom{n}{3} = \frac{n(n-1)(n-2)}{3!}$. If n is a positive integer, the coefficients of the rth term from the beginning and the rth from the end are equal.

The binomial $(a \pm b)^n$ may be written as $a^n(1 \pm x)^n$, where $x = b/a$. It is often more convenient to expand the second form than the first. The following special forms can be used if n is any positive integer; and for any negative or fractional value of n, if x lies between 0 and 1:

$$(1 \pm x)^n = 1 \pm nx + \frac{n(n-1)}{1\cdot 2}x^2 \pm \frac{n(n-1)(n-2)}{1\cdot 2\cdot 3}x^3 + \frac{n(n-1)(n-2)(n-3)}{1\cdot 2\cdot 3\cdot 4}x^4 \pm \ldots$$

$$\frac{1}{1 \pm x} = (1 \pm x)^{-1} = 1 \mp x + x^2 \mp x^3 + x^4 \mp x^5 + \ldots$$

$$\sqrt{1 \pm x} = (1 \pm x)^{1/2} = 1 \pm \frac{1}{2}x - \frac{1}{2\cdot 4}x^2 \pm \frac{1\cdot 3}{2\cdot 4\cdot 6}x^3 - \frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6\cdot 8}x^4 \pm \frac{1\cdot 3\cdot 5\cdot 7}{2\cdot 4\cdot 6\cdot 8\cdot 10}x^5 - .$$

$$\frac{1}{\sqrt{1 \pm x}} = (1 \pm x)^{-1/2} = 1 \mp \frac{1}{2}x + \frac{1\cdot 3}{2\cdot 4}x^2 \mp \frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}x^3 + \ldots$$

Common Progression Series

A Progression is a sequence of terms which proceed according to some fixed law. *A series* may be formed by writing an expression indicating the summation of the terms appearing in a progression.

An Arithmetic Progression is a sequence of terms each of which differs from the preceding by the same number d, called the *common difference.* If n = number of terms, a = first term, l = last term, s = sum of n terms, then $l = a + (n - 1)d$, and $s = \frac{n}{2}(a + l)$. The arithmetic mean of two numbers is the number which placed between them would make with them an arithmetic progression. Thus, the arithmetic mean of m, n is $(m + n)/2$.

Example: Given the series $3 + 5 + 7 + \ldots$ to 10 terms. Here $n = 10$; $a = 3$; $d = 2$; hence $l = 3 + (10 - 1) \times 2 = 21$, and $s = (10/2)(3 + 21) = 120$.

A Geometric Progression is a sequence of terms each of which is obtained from the preceding by multiplying it by a fixed number r, called the *ratio.* If n = number of terms, a = first term, l = last term, s = sum of n terms, then $l = ar^{n-1}$, $s = (rl - a)/(r - 1) = a(1 - r^n)/(1 - r)$. The geometric mean of two numbers is the number which placed between them would make with them a geometric progression. Thus, the geometric mean of m, n is $\sqrt{mn}$.

Example: Given the series $3 + 6 + 12 + \ldots$ to 6 terms. Here $n = 6$; $a = 3$; $r = 2$; hence $l = 3 \times 2^{(6-1)} = 96$, and $s = (2 \times 96 - 3)/(2 - 1)$, or $= 3\,(1 - 2^6)/(1 - 2) = 189$.

If $|r| < 1$ and the number of terms is increased indefinitely, $s \to a/(1 - r)$ as $n \to \infty$.

Example: Given the infinite series $1/2 + 1/4 + 1/8 + \ldots$. Here $a = 1/2$ and $r = 1/2$; hence $s \to (1/2)/(1 - 1/2) = 1$ as $n \to \infty$.

An Harmonic Progression is a sequence of terms whose reciprocals form an arithmetic progression. The harmonic mean of two numbers is the number which placed between them would make with them an harmonic progression. Thus, the harmonic mean of m, n is $2\,mn/(m + n)$.

The Relation between Arithmetic, Geometric, and Harmonic Means of two numbers is expressed by the equality $G^2 = AH$, where G = geometric mean, A = arithmetic mean, and H = harmonic mean.

Other Series

1. $1 + 2 + 3 + 4 + \ldots + (n - 1) + n = n\,(n + 1)/2$.
2. $p + (p + 1) + (p + 2) + \ldots + (q - 1) + q = (q + p)(q - p + 1)/2$.
3. $2 + 4 + 6 + 8 + \ldots + (2n - 2) + 2n = n\,(n + 1)$.
4. $1 + 3 + 5 + 7 + \ldots + (2n - 3) + (2n - 1) = n^2$.
5. $1^2 + 2^2 + 3^2 + 4^2 + \ldots + (n - 1)^2 + n^2 = n\,(n + 1)(2n + 1)/6$.
6. $1^3 + 2^3 + 3^3 + 4^3 + \ldots + (n - 1)^3 + n^3 = n^2\,(n + 1)^2/4$.

$$\left.\begin{array}{ll}
7. & \dfrac{1 + 2 + 3 + 4 + 5 \ldots + n}{n^2} \to \dfrac{1}{2} \\[2ex]
8. & \dfrac{1 + 2^2 + 3^2 + 4^2 + \ldots + n^2}{n^3} \to \dfrac{1}{3} \\[2ex]
9. & \dfrac{1 + 2^3 + 3^3 + 4^3 + \ldots + n^3}{n^4} \to \dfrac{1}{4}
\end{array}\right\} \text{ as } n \to \infty.$$

16. APPROXIMATE FORMULAS

The Approximate Formulas listed below are sufficiently accurate to be satisfactory in the solution of many practical problems. Care must be taken, however, to use them only under the conditions specified.

(*a*) If $|x|$ and $|y|$ are small compared with 1:

1. $(1 \pm x)^2 = 1 \pm 2x$.
2. $(1 \pm x)^{1/2} = 1 \pm \frac{x}{2}$.
3. $\frac{1}{1 \pm x} = 1 \mp x$.
4. $(1 + x)(1 + y) = 1 + x + y$.
5. $(1 + x)(1 - y) = 1 + x - y$.

$$\left.\begin{array}{ll}
6. & e^x = 1 + x + \dfrac{x^2}{2} \text{ (where } e = 2.71828\text{)}. \\[2ex]
7. & \log_e (1 \pm x) = \pm x - \dfrac{x^2}{2} \pm \dfrac{x^3}{3}. \\[2ex]
8. & \log_e \left(\dfrac{1 + x}{1 - x}\right) = 2\left(x + \dfrac{x^3}{3} + \dfrac{x^5}{5}\right).
\end{array}\right\} \text{ (Last term often may be omitted).}$$

(*b*) If $|x|$ is small compared with a and $a > 0$:

9. $a^x = 1 + x \log_e a + \frac{x^2}{2} (\log_e a)^2$. (Last term often may be omitted.)

(*c*) If a and b are nearly equal and both > 0:

10. $\sqrt{ab} = \frac{a+b}{2}$.

(*d*) If b is small compared with a and both > 0:

11. $\sqrt{a^2 \pm b} = a \pm \frac{b}{2a}$.

12. $\sqrt{a^3 \pm b} = a \pm \frac{b}{3a^2}$.

13. $\sqrt{a^2 + b^2} = 0.960\,a + 0.398\,b$. This is within 4 per cent of the true value if $a > b$. A closer approximation is $\sqrt{a^2 + b^2} = 0.9938\,a + 0.0703\,b + 0.3567\,\frac{b^2}{a}$.

14. $\sqrt{a^2 + b^2 + c^2} = 0.939\,a + 0.389\,b + 0.297\,c$. This is within 6 per cent of the true value if $a > b > c$. For instance, for the numbers 43, 42, and 41, the error < 5.2 per cent.

(*e*) If $|x|$ is less than $\frac{\pi}{18}$:

$$\left.\begin{aligned} &15.\ \sin x = x - \frac{x^3}{6}. \\ &16.\ \cos x = 1 - \frac{x^2}{2}. \\ &17.\ \tan x = x + \frac{x^3}{3}. \end{aligned}\right\} \text{(Last term often may be omitted.)}$$

(Note: If $x = 8° = \frac{8\pi}{180} = 0.13963$, $\sin x = x - {}^1/_6\, x^3 = 0.13918$, which is one unit in error in the fifth decimal place. If the absolute value of the angle is less than 5°, the values of x and $\sin x$ do not differ more than one unit in the fourth decimal place.)

(*f*) If $|y|$ is less than $\frac{\pi}{36}$ and small compared with $|x|$:

18. $\sin (x \pm y) = \sin x \pm y \cos x$.

19. $\cos (x \pm y) = \cos x \mp y \sin x$.

20. $\tan (x \pm y) = \tan x \pm \frac{y}{\cos^2 x}$.

17. PERMUTATIONS AND COMBINATIONS

A Permutation of n things is any *arrangement* of any number of them in a definite order. The possible number of *different* arrangements of n things taken r at a time is designated ${}_nP_r$.

For n things all different:

$$ {}_nP_r = n(n-1)(n-2)\ldots(n-r+1) = \frac{n!}{(n-r)!}$$

(Particular cases: ${}_nP_1 = n$; ${}_nP_n = n!$.)

Example: How many different arrangements of the letters in the word "black" can be made, using three at a time? Solution: ${}_5P_3 = 5 \times 4 \times 3 = 60$.

For n things taken all at a time of which n_1 are alike, n_2 others are alike, etc.:

$$ {}_nP_n = \frac{n!}{n_1!\, n_2!\, n_3! \ldots}$$

Example: How many different arrangements can be made of the letters in the word "level"? Solution: $P = \frac{5!}{2!\,2!} = 30$.

A Combination of n things is any *group* of any number of them without reference to their order within the group. The possible number of *different* groups of n things taken r at a time is designated ${}_nC_r$.

For n things all different:

$$ {}_nC_r = \frac{{}_nP_r}{r!} = \frac{n(n-1)(n-2)\ldots(n-r+1)}{r!} = \frac{n!}{r!(n-r)!}$$
$$ = \frac{n(n-1)(n-2)\ldots(r+1)}{(n-r)!} = \frac{{}_nP_{n-r}}{(n-r)!} = {}_nC_{n-r}$$

(Particular cases: ${}_nC_1 = n$; ${}_nC_n = 1$.)

Example: In how many ways can 9 books be selected from a set of 11?

Solution: ${}_{11}C_9 = {}_{11}C_2 = \frac{11 \times 10}{2!} = 55.$

For n things all different, the total number of combinations taken any number at a time is:

$$ {}_nC_1 + {}_nC_2 + \ldots + {}_nC_{n-1} + {}_nC_n = 2^n - 1. $$

Example: How many different sums can be formed from a penny, a nickel, a dime, a quarter, and a half dollar? Solution: $2^5 - 1 = 31$.

For two groups of m and n things, respectively, all different, the number of combinations of $(r + s)$ things, r from the first group and s from the second group, is:

$$ {}_mC_r \cdot {}_nC_s = \frac{m!\,n!}{r!\,s!(m-r)!(n-s)!} $$

18. PROBABILITY

The Probability *that an event will happen* is the ratio of the number of favorable cases to the entire number of possible cases, provided all cases are *equally likely* to occur. *The probability of failure* is unity minus the probability of happening. The *odds* in favor of the event are given by the ratio of probability of happening to probability of failure.

Example: From an urn containing 5 black and 4 white balls, 3 balls are drawn at random. What is the probability that 2 will be black and 1 white? Solution: From 9 balls, 3 may be drawn in ${}_9C_3 = 9 \times 8 \times 7 \div 3! = 84$ ways. The number of favorable cases is ${}_5C_2 \cdot {}_4C_1 = (5 \times 4/2) \times 4 = 40$. Hence the required probability is ${}^{40}/_{84} = {}^{10}/_{21}$, i.e., 10 chances in 21.

Events of a set are *independent* if the occurrence of any one of them does not affect the occurrence of others; otherwise, they are *dependent*. Events of a set are *mutually exclusive* if the occurrence of any one of them on a particular occasion excludes the occurrence of any other on that occasion.

The probability of *simultaneous occurrence* of two *independent events* whose respective probabilities are a and b is ab. The probability of *occurrence of one or the other* of two *mutually exclusive* events whose respective probabilities are a and b is $a + b$.

Example: The probability of drawing a jack from a full pack of cards is ${}^1/_{13}$. The probability of drawing a spade is ${}^1/_4$. Hence the probability of drawing the jack of spades is $({}^1/_{13}) \times ({}^1/_4) = {}^1/_{52}$. The probability of drawing a jack or an ace is ${}^1/_{13} + {}^1/_{13} = {}^2/_{13}$.

MATHEMATICS OF FINANCE

By J. L. Barnes

19. INTEREST AND DISCOUNT

Interest is *money* paid for the use of *capital* during a period of time. The capital or sum of money borrowed is called the *principal.*

The Rate of Interest is the ratio of the interest earned *in a unit time* to the principal. It is usually expressed as the per cent paid for the use of the principal for *one year.*

Simple Interest, I, is computed by the relation

$$ I = P\,i\,t \tag{1} $$

where P is the principal, i the rate of interest, and t the time in years.

The *sum*, S, due at the end of the interval of time, t, is,

$$ S = P + I \tag{2} $$

In Ordinary Simple Interest calculations, a month is regarded as 30 days, and a year as 12 months, or 360 days. Thus, if d denotes the time in days

$$ I = P\,i\,\frac{d}{360} \tag{3} $$

Exact Simple Interest. Simple interest computed by taking the exact number of days or 365 days for the year is called *exact simple interest.* Thus

$$ I_e = P\,i\,\frac{d}{365} \tag{4} $$

where I_e is the exact simple interest. To facilitate calculation Table I shows the number of days between two dates, a year or less apart, and Table II the exact simple interest on $1000 for the number of days indicated.

Example: To obtain the number of days between April 13, and December 4, determine the number of days *from* April *to* December, 244, subtract 13, and add 4. Thus, $244 - 13 + 4 = 235$ days.

Table I. Days between the Same Dates of Different Months

(Leap year adds one day in February.)

Compound Interest is the interest on the principal and its unpaid interest combined at regular intervals. The sum S, or amount to which P will accumulate in n equal conversion periods or time units, is,

$$S = P(1 + i)^n \tag{5}$$

If there are m conversion periods per year, n years, and j is the nominal or quoted interest rate per year,

$$S = P\left(1 + \frac{j}{m}\right)^{mn} \tag{6}$$

Values of the sum, S, if $P = 1$ (amount of one) may be obtained from Table III for values of n from 1 to 50 at different rates, i. The value of S may also be calculated with the aid of logarithms, thus

$$\log S = \log P + n \log (1 + i) \tag{7}$$

Example: To find the amount of $3900 at 3 1/2 per cent compounded annually for 29 years proceed in this way. (*a*) Enter the table at the column headed 3 1/2 per cent and opposite $n = 29$ read 2.71188 . . , the amount of 1. (*b*) Multiply this tabular value by 3900 to obtain the result. To use the table for a value of time not given use the relation that the amount of 1 for $n_1 + n_2$ years is equal to the amount for n_1 years times the amount for n_2 years. Thus if the table extends to only 50 periods of time, the amount of 1 for 67 periods at the rate 0.04 is $(1.04)^{67} = (1.04)^{50} \cdot (1.04)^{17}$, and the two factors of the second member can be read from the table.

The Present Value of a sum S due in n years is defined as the principal P which drawing a given rate of (compound) interest i will in n years amount to S, or in which $v = (1 + i)^{-1}$

$$P = S(1 + i)^{-n} = Sv^n, \tag{8}$$

Values of P or v^n for $S = 1$, may be obtained from Table IV.

Table IV. Present Value of 1

$$v^n = (1 + i)^{-n}$$

Example: The present value of $3900 due in 17 years with the (compound) interest rate 3 1/2 per cent is found in the following way: (*a*) Enter the table at the column headed 3 1/2 per cent and opposite $n = 17$ read 0.55720 . . . , the present value of 1. (*b*) Multiply this tabular value by 3900 to obtain the result.

Discount is the money paid at the beginning of an interval of time for the use of capital during that interval. Denote the rate of interest by i, and the *rate of discount* by d. Then

$$d = \frac{i}{1+i} \tag{9}$$

In place of the type of discount just defined, which can be called *compound discount*, it is usual practice for the banker to give for each unit of the bill an amount $1-d/m$, in which d is the rate of discount per year and $1/m$ indicates the fractional part of a year. For fractional parts of a year, then, the banker uses what is called *simple discount*.

The Average Due Time for a number of sums, due at different times, is the time at which they may all be paid with due regard to the equities involved. Denote by $S_1, S_2, \ldots, S_r$ the sums due at the ends of $n_1, n_2, \ldots, n_r$ years, respectively, and the average due time by T. On the assumption that money is worth a (compound) rate of interest i,

$$T = \frac{\log \sum_{k=1}^{r} S_k - \log \sum_{k=1}^{r} \frac{S_k}{(1+i)^{n_k}}}{\log (1+i)} \tag{10}$$

If the times are small, the following approximate relation may be employed:

$$T \approx \frac{\sum_{k=1}^{r} n_k S_k}{\sum_{k=1}^{r} S_k} \tag{11}$$

20. ANNUITIES AND SINKING FUNDS

An Annuity Certain is a succession of periodic payments for a definite (certain) term of years. The first payment of an annuity is supposed to be made at the end of the first period. The sum or amount to which the payments accumulate is called the *amount of the annuity*. Ordinarily the nominal rate of interest j and the number m of conversion intervals per year are known, so the effective rate i can be determined. It is given by

$$i = \left(1 + \frac{j}{m}\right)^m - 1 \tag{12}$$

Denote the amount of an annuity of 1 per year payable annually for n years by $s_{\overline{n}|}$. Then

$$s_{\overline{n}|} = \frac{(1+i)^n - 1}{i} \tag{13}$$

The yearly payment of an annuity is called the *annual rent*. Denote the annual rent of an annuity by R, and the amount for n years by S. Then

$$S = Rs_{\overline{n}|} = \frac{R[(1+i)^n - 1]}{i} \tag{14}$$

This relation may be solved for n,

$$n = \frac{\log (Si + R) - \log R}{\log (1+i)}, \tag{15}$$

a relation which is exact if n is an integer and approximate if n is not an integer.

The Present Value of an Annuity Certain is the sum of the present values of all the future payments. Denote the present value of an annuity certain of 1 per year for n years by $a_{\overline{n}|}$ and the effective rate of interest by i. Then

$$a_{\overline{n}|} = \frac{1 - (1+i)^{-n}}{i} \tag{16}$$

Denote the present value of an annuity certain of R per year by A. Then

$$A = Ra_{\overline{n}|} = \frac{R[1 - (1+i)^{-n}]}{i} \tag{17}$$

As in the preceding paragraph,

$$i = \left(1 + \frac{j}{m}\right)^m - 1 \qquad (18)$$

Table V. Amount of 1 per Annum

$$s_{\overline{n|}} = \frac{(1+i)^n - 1}{i}$$

Example: The amount of an annuity certain yielding an annual rent of $400 for 10 years with effective interest at 4 per cent may be found in the following way: (*a*) Enter the table in the column headed 4 per cent and opposite n = 10 read 12.0061 . . , the amount of 1. (*b*) Multiply this tabular value by 400 to obtain the result.

Table VI. Present Value of 1 per Annum

$$a_{\overline{n}|} = \frac{1 - (1+i)^{-n}}{i}$$

n	2 1/2%	3%	3 1/2%	4%	4 1/2%	5%	5 1/2%	6%	7%	8%

Example: The present value of $39 per year for 20 years with an effective interest rate of 5 per cent is found in the following way: (*a*) Enter the table at the column headed 5 per cent and opposite $n = 20$ read 12.4622 . . , the present value of 1 per year. (*b*) Multiply the tabular value by 39 to obtain the result.

The Annuity Which 1 Will Purchase is the annuity whose present value is 1. Denote the annual rent of such an annuity by r. Then

$$r = \frac{1}{a_{\overline{n}|}} \tag{19}$$

If the purchase price is A, the annual rent is

$$R = rA = \frac{A}{a_{\overline{n}|}} = \frac{Ai}{1 - (1+i)^{-n}} \tag{20}$$

Table VII. Annuity Which 1 Will Purchase

$$\frac{1}{a_{\overline{n}|}} = \frac{i}{1-(1+i)^{-n}} \quad \text{or} \quad \frac{1}{s_{\overline{n}|}} + i$$

Example: The annual rent for 10 years which $3900 will purchase at an effective interest rate of 5 per cent is found in the following way: (*a*) Enter the table at the column headed 5 per cent and opposite $n = 10$ read 0.129505 . . , the rent purchased by 1. (*b*) Multiply the tabular value by 3900 to obtain the result.

A Sinking or Amortization Fund is a fund set aside to provide a definite sum (usually for canceling a debt) at a certain time; it is usually created by equal and regular contributions and their interest earnings, compounded; that is, by an annuity and its interest earnings. Denote the annual instalment or rent required by R, the amount of the sinking fund by S, the number of years for its creation by n, and the effective rate of interest by i. Then

$$R = \frac{S}{s_{\overline{n}|}} = \frac{Si}{(1+i)^n - 1} \tag{21}$$

Table VIII. Annuity Which Will Amount to 1 (Sinking Fund)

$$\frac{1}{s_{\overline{n|}}} = \frac{i}{(1+i)^n - 1} \quad \text{or} \quad \frac{1}{a_{\overline{n|}}} - i$$

Example: The annual instalment required to create a fund of $22,000 in 25 years at 4 per cent may be found in the following way: (*a*) Enter the table at the column headed 4 per cent and opposite $n = 25$ read 0.024012 . . . , the annual instalment to accumulate 1. (*b*) Multiply this tabular value by 22,000 to obtain the result.

A Life Annuity* is one whose payments continue only during the lifetime of the recipient. Its cost and present value depend not only upon the rate of interest but also upon the *probability of living* and differs in this respect from an annuity certain.

---

* For the theory of life insurance computations see Mathematical Theory of Finance, by Putnam, John Wiley & Sons, Inc.

Mortality tables (Table IX) are constructed from the experience of agencies such as insurance companies to indicate the probable deaths occurring in each succeeding year from a chosen initial group. Denote the age of the group by x, the number living by l_x, the number dying in the year interval from x to $x + 1$ by d_x, the probability of living during the year x by p_x, and the probability of dying within the year by q_x, then:

$$d_x = l_x - l_{x+1} \tag{22}$$

$$p_x = \frac{l_{x+1}}{l_x} \tag{23}$$

$$q_x = \frac{d_x}{l_x} = 1 - p_x \tag{24}$$

The probability of a person age x living n years is:

$$_np_x = \frac{l_{x+n}}{l_x} \tag{25}$$

and of not living n years is:

$$_nq_x = 1 - {}_np_x \tag{26}$$

Table IX. American Experience Table of Mortality

Age x	Number living l_x	Number of deaths d_x	Yearly probability of dying q_x	Yearly probability of living p_x	Age x	Number living l_x	Number of deaths d_x	Yearly probability of dying q_x	Yearly probability of living p_x

Present Value of a Life Annuity. If p is the probability of receiving a certain sum of money S, the value of the *expectation* is pS and the present value of S due in n years is,

$$pS(1 + i)^{-n} = pSv^n \tag{27}$$

The present value of the expectation of a person, x years of age, who is to receive 1 if he lives n more years is called the *n-year pure endowment of 1* denoted by ${}_nE_x$.

$${}_nE_x = {}_np_x \cdot v^n \tag{28}$$

Similarly, the present value of a *life annuity* of 1 beginning at age $x + m$ to a person of age x is,

$$a_{x+m} = \sum_{n=m}^{95-x} {}_nE_x, \tag{29}$$

since 95 is the upper bound of age in the American Experience Table of Mortality.

GEOMETRY

By Janvier M. Rice

21. GEOMETRIC CONCEPTS

Definitions and fundamental properties of important geometric figures and geometric relations are given below. In general, very common and well-known terms (as point, line, radius, etc.) are not discussed.

Plane Angles

A Plane Angle measures the extent or degree to which two straight lines deviate in direction. Straight lines that have the same direction do not meet or intersect in finite distances and are called *parallel lines*. Two straight lines that are not parallel but lie in the same plane intersect. The point of intersection of non-parallel lines is the *vertex* of the angle between them. The *size of the angle* is the extent of the opening between the lines and is independent of their length. The size of an angle generated by a revolving line varies from zero to one *complete revolution* as the line is rotated about a vertex to its original position.

A Degree (°) is $^1/_{360}$ of a revolution (or *perigon*) and is divided into 60 units called *minutes* (′) which in turn are divided into 60 units called *seconds* (″).

A Radian is a *central angle* which intercepts a *circular arc* equal to its *radius*. One radian, therefore, equals $360/2\pi$ degrees or 57.295779513°, and 1° = 0.017453293 radian.

An Angle of 90° is called a *right angle*, and the lines that form it are said to be *perpendicular*. An angle less than a right angle is called *acute*. An angle greater than a right angle but less than 180° is called *obtuse*. If the sum of two angles equals 90°, they are said to be *complementary* to each other, and if their sum is 180°, *supplementary* to each other.

Polygons

A Polygon, or *plane rectilinear figure*, is a portion of a plane bounded by straight lines.

A Triangle is a polygon of three sides. It is *isosceles* if two sides (and their opposite angles) are equal; it is *equilateral* if all three sides (and all three angles) are equal.

A Quadrilateral is a polygon of four sides. This classification includes the *trapezium* having no two sides parallel; the *trapezoid* having two opposite sides parallel (*isosceles trapezoid* if the non-parallel sides are equal); and the *parallelogram* having both pairs of opposite sides parallel and equal. The parallelogram includes the *rhomboid* having no right angles and, in general, adjacent sides not equal; the *rhombus* having no right angles but all sides equal; the *rectangle* having only right angles and, in general, adjacent sides not equal; and the *square* having only right angles, and all sides equal.

Similar Polygons have their respective angles equal and their corresponding sides proportional.

A Regular Polygon has all sides equal and all angles equal. An *equilateral triangle* and a *square* are regular polygons.

Other Polygons classified according to number of sides are: (5) *pentagon*; (6) *hexagon*; (7) *heptagon*; (8) *octagon*; (9) *enneagon* or *nonagon*; (10) *decagon*; (12) *dodecagon*. Two regular polygons of the same number of sides are *similar*.

Properties of Triangles.

General Triangle. The sum of the angles equals 180°. $\angle XAB$ (Fig. 1) is an *exterior angle* of $\triangle ABC$ and equals the sum of the opposite *interior angles* (i.e., $\angle XAB = \angle B + \angle C$). A *median* of a triangle is a line joining a vertex to the mid-point of the opposite side. The three medians meet at the *center of gravity*, G, and G trisects each median (i.e., $AG = {}^2/_3\,AD$, etc.) *Bisectors of angles* of a triangle (Fig. 2) meet in a point M equidistant from all sides. M is the center of the *inscribed circle* (tangent to all sides), or the *incenter* of the triangle. An angle bisector divides the opposite side into segments proportional to the adjacent sides of the angle (i.e., $AE/EC = AB/BC$, etc.). An *altitude* of a triangle is a perpendicular from a vertex to the opposite side. The three altitudes meet in a point called the *orthocenter*. The *perpendicular bisectors* of the sides of a triangle (Fig. 3) meet in a point O equidistant from all vertices. O is the center of the *circumscribed circle* (passing through all vertices), or the *circumcenter* of the triangle. The longest side of a triangle is opposite the largest angle, and vice versa. The line joining the mid-points of two sides of a triangle is parallel to the third side and half its length. If two triangles are mutually equiangular, they are *similar*, and their corresponding sides are proportional.

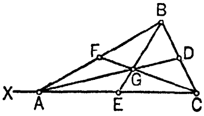

FIG. 1

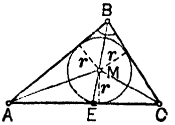

FIG. 2

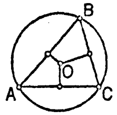

FIG. 3

Orthogonal Projection. In Figs. 4 and 5, AE is the orthogonal projection of AB on AC, BE being perpendicular to AC. The square of the side opposite an acute angle equals the sum of the squares of the other two sides diminished by twice the product of one of those sides by the orthogonal projection of the other side upon it. In Fig. 4, $a^2 = b^2 + c^2 - 2b \cdot AE$. The square of the side opposite an obtuse angle equals the sum of the squares of the other two sides increased by twice the product of one of those sides by the orthogonal projection of the other side upon it. In Fig. 5, $a^2 = b^2 + c^2 + 2b \cdot AE$.

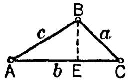

FIG. 4

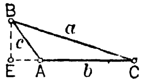

FIG. 5

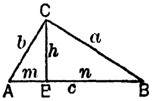

FIG. 6

Right Triangle. In Fig. 6, let h be the *altitude* drawn from the vertex of right angle C to the *hypotenuse* c. Then $\angle A + \angle B = 90°$; $c^2 = a^2 + b^2$; $h^2 = mn$; $b^2 = cm$; $a^2 = cn$; median from $C = c/2$.

Isosceles Triangle. Two sides are equal and their opposite angles are equal. If a straight line from the vertex at which the equal sides meet bisects the base, it also bisects the vertical angle and is perpendicular to the base.

Plane Curvilinear Figures

An *arc* is a part of a curve. A *chord* is a straight line joining two points on a curve (i.e., joining the extremities of an arc). A *segment* of a curve is that portion of its plane included between a concave arc and its chord. An angle *intercepts* an arc cut off by its sides; the arc *subtends* the angle. Two curves are *tangent* to each other at a point if, in passing the point, they touch each other. If one of the "curves" is a straight line, the line itself is called a *tangent* to the curve.

A Circle is a closed plane curve (or the surface bounded by the curve), all the points of which are equidistant from a *center* point within. A *central angle* is one whose vertex is at the center and whose sides are two radii. A *sector* of a circle is the part of its plane which is included between an arc and two radii drawn to its extremities. A *secant* of a circle is a straight line intersecting it in two points. Parallel secants (or tangents) intercept equal arcs. A tangent line meets a circle in only one point and is perpendicular to the radius to that point. If a radius is perpendicular to a chord, it bisects both the chord and the arc intercepted by the chord. If two circles are tangent to each other, the line of centers passes through the point of contact; if the circles intersect, the line of centers bisects the common chord at right angles. In Fig. 8, the product of linear segments AC and AE equals the product of linear segments AB and AF. In Fig. 9, the product of the whole secant AB and its external segment AE equals the product of the whole secant AC and its external segment AF. In Fig. 10, the product of the whole secant AD and its external segment AC equals the square of tangent AB (or AE). Also $\angle ABE = \angle AEB$.

Angle Measurement. Considering the arc of a circle to be expressed in terms of the central angle which it subtends, the arc may be said to contain a certain number of degrees and hence be used to express the measurement of other angles related to the circle. On this basis, an entire circle equals 360°. The *inscribed angle* formed by two chords intersecting on a circle equals half the arc intercepted by it. Thus, in Fig. 7, $\angle BAC = {}^1/_2$ arc BC. An angle inscribed in a semicircle is a right angle. The angle formed by a tangent to a circle and a chord having one extremity at the point of contact equals half the arc intercepted by the chord. In Fig. 7, $\angle BAT = {}^1/_2$ arc BCA. The angle formed by two chords intersecting within a circle equals half the sum of the intercepted arcs. In Fig. 8, $\angle BAC$ (or $\angle EAF$) $= {}^1/_2$ (arc BC + arc EF), and $\angle BAE$ (or $\angle CAF$) $= {}^1/_2$ (arc BE + arc CF). The angle formed by two secants, or two tangents, or a secant and a tangent, intersecting outside a circle, equals half the difference of the intercepted arcs. In Fig. 9, $\angle BAC = {}^1/_2$ (arc BC − arc EF). In Fig. 10, $\angle BAE = {}^1/_2$ (arc BDE − arc BCE), and $\angle BAD = {}^1/_2$ (arc BD − arc BC).

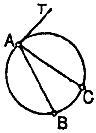

FIG. 7

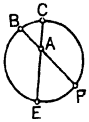

FIG. 8

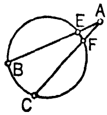

FIG. 9

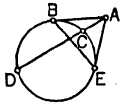

FIG. 10

Other Plane Curves appearing in the mensuration table on pp. 2–38 to 2–40 are defined and discussed in the section on analytic geometry.

Non-Planar Angles

A Dihedral Angle is the opening between two intersecting planes. In Fig. 11, P–BD–Q is a dihedral angle of which the two planes are the *faces* and their line of intersection DB is the edge. A *plane angle* which measures a dihedral angle is an angle formed by two lines, one in each face, drawn perpendicular to the edge at the same point (as $\angle ABC$). A *right dihedral angle* is one whose plane angle is a right angle. Through a given line oblique or parallel to a given plane, one and only one plane can be passed perpendicular to the given plane. The line of intersection CD (Fig. 12) is the *orthogonal projection* of line AB upon plane P. The *angle between a line and a plane* is the angle that the line (produced if necessary) makes with its orthogonal projection on the plane. This angle is the least angle which the line makes with any line in the plane.

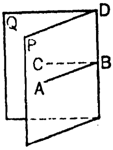

FIG. 11

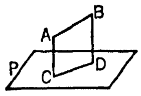

FIG. 12

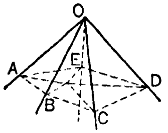

FIG. 13

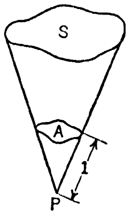

FIG. 14

A Polyhedral Angle is the opening of three or more planes which meet in a common point. In Fig. 13, O–$ABCDE$ is a polyhedral angle of which the intersections of the planes, as OA, OB, etc., are the *edges*; the portions of the planes lying between the edges are the *faces*; and the common point O is the *vertex*. Angles formed by adjacent edges, as angles AOB, BOC, etc., are *face angles*. A polyhedral angle is called a *trihedral angle* if it has three faces; a *tetrahedral angle* if it has four faces; and so on.

A Solid Angle measures the opening between surfaces, either planar or non-planar, which meet in a common point. The polyhedral angle is a special case. In Fig. 14 the solid angle at any point P, subtended by any surface S, is equal numerically to the portion

A of the surface of a sphere of unit radius which is cut out by a conical surface with vertex at P and having the perimeter of S for base. The *unit solid angle* is the *steradian* and equals the central solid angle which intercepts a spherical area (of any shape) equal to the (radius)^2. The total solid angle about a point equals 4π steradians.

A Spherical Angle is the opening between two arcs of great circles drawn from the same point (*vertex*), and is measured by the plane angle formed by tangents to its sides at its vertex. If the planes of the great circles are perpendicular, the angle is a *right spherical angle.*

Polyhedrons

A Polyhedron is a solid bounded by plane surfaces.

A Prism is a polyhedron of which two faces (the *bases*) are congruent polygons in parallel planes and the other (*lateral*) faces are parallelograms whose planes intersect in the *lateral edges.* Prisms are *triangular, rectangular, quadrangular,* and so on, according as their bases are triangles, rectangles, quadrilaterals, and so on. A *right prism* has its lateral edges perpendicular to its bases. A prism whose bases are parallelograms is a *parallelepiped*; if in addition the edges are perpendicular to the bases, it is a *right parallelepiped.* A *rectangular parallelepiped* is a *right* parallelepiped whose bases are rectangles. A *cube* is a parallelepiped whose six faces are squares. A *truncated prism* is that part of a prism included between a base and a section made by a plane oblique to the base. A *right section* of a prism is a section made by a plane which cuts all the lateral edges and is perpendicular to them.

A Prismatoid is a polyhedron of which two faces (the *bases*) are polygons in parallel planes and the other (*lateral*) faces are triangles or trapezoids with one side common with one base and the opposite vertex or side common with the other base.

A Pyramid is a polyhedron of which one face (the *base*) is a polygon and the other (*lateral*) faces are triangles meeting in a common point called the *vertex* of the pyramid and intersecting one another in its *lateral edges.* Pyramids are *triangular, quadrangular,* and so on, according as their bases are triangles, quadrilaterals, and so on. A *regular pyramid* (or *right pyramid*) has for its base a regular polygon whose center coincides with the foot of the perpendicular dropped from the vertex to the base. A *frustum of a pyramid* is the portion of a pyramid included between its base and a section parallel to the base. If the section is not parallel to the base, a *truncated pyramid* results.

A Regular Polyhedron has all faces formed of congruent regular polygons and all polyhedral angles equal. The only regular polyhedrons possible are the five types discussed in the mensuration table, p. 2–41.

A Tetrahedron is a polyhedron of four faces. It may be described also as a triangular pyramid, and any one of its four triangular faces may be considered as the base. The four perpendiculars erected at circumcenters of the four faces meet in a point equidistant from all vertices, which is the center of the circumscribed sphere. The four *medians,* joining each vertex with the center of gravity of the opposite face, meet in a point, which is the *center of gravity* of the tetrahedron. This point is three-fourths of the distance from each vertex along a median. The four altitudes meet in a point, called the *orthocenter* of the tetrahedron. The six planes bisecting the six dihedral angles meet in a point equidistant from all faces, this being the center of the inscribed sphere.

Solids Having Curved Surfaces

A Cylinder is a solid bounded by two parallel plane surfaces (the *bases*) and a cylindrical *lateral* surface. A *cylindrical surface* is a surface generated by the movement of a straight line (the *generatrix*) which constantly is parallel to a fixed straight line and touches a fixed curve (the *directrix*) not in the plane of the fixed straight line. The generatrix in any position is an *element* of the cylindrical surface. A *circular cylinder* is one having circular bases. A *right cylinder* is one whose elements are perpendicular to its bases. A *truncated cylinder* is the part of a cylinder included between a base and a section made by a plane oblique to the base. A *right section* of a cylinder is a section made by a plane which cuts all the elements and is perpendicular to them.

A Cone is a solid bounded by a conic *lateral* surface and a plane (the *base*) which cuts all the elements of the conic surface. A *conic surface* is a surface generated by the movement of a straight line (the *generatrix*) which constantly touches a fixed plane curve (the *directrix*) and passes through a fixed point (the *vertex*) not in the plane of the fixed curve. The generatrix in any position is an *element* of the conic surface. A *circular cone* is one having a circular base. A *right cone* is a circular cone whose center of the base coincides with the foot of the perpendicular dropped from the vertex to the base. A *frustum of a cone* is the portion of a cone included between its base and a section parallel to the base.

A Sphere is a solid bounded by a surface all points of which are equidistant from a point within called the *center*. Every plane section of a sphere is a circle. This circle is a *great circle* if its plane passes through the center of the sphere; otherwise, it is a *small circle*. *Poles* of such a circle are the extremities of the diameter of the sphere which is perpendicular to the plane of the circle. Through two points on a spherical surface, not extremities of a diameter, one great circle can be passed. The shortest line that can be drawn on the surface of a sphere between two such points is an arc of a great circle less than a semicircumference joining those points. If two spherical surfaces intersect, their line of intersection is a circle whose plane is perpendicular to the line of centers, and whose center lies on this line.

A Spherical Sector is the portion of a sphere generated by the revolution of a circular sector about a diameter of the circle of which the sector is a part. A *hemisphere* is half of a sphere.

A Spherical Segment is the portion of a sphere contained between two parallel plane sections (the *bases*), one of which may be tangent to the sphere (in which case there is only one base). The term "segment" also is applied in an analogous manner to various solids of revolution, the planes in such cases being perpendicular to an axis. A *zone* is the portion of a spherical surface included between two parallel planes.

A Spherical Polygon is a figure on a spherical surface bounded by three or more arcs of great circles. The sum of the angles of a spherical triangle (polygon of three sides) is greater than two right angles and less than six right angles.

Other Solids appearing in the mensuration table on pp. 2–41 to 2–44, if not sufficiently defined by their figures, may be found discussed in the section on analytic geometry.

22. MENSURATION

Mensuration treats of the measurement of lines, surfaces, and solids, in terms of length, area, and volume, respectively. Table I furnishes important mensuration formulas for the more common plane figures and solids. In addition to these formulas, useful data on circumferences and areas of circles, length of their arcs, and various properties of their segments, as well as data on volumes of spheres, may be found in Tables 7 of Section 1. The area of the surface of a sphere may be obtained by multiplying the area of a great circle (Table 7) by 4.

Perimeters (or Circumferences) of Similar Figures are to each other as their respective linear dimensions. Thus, the perimeter of a quadrilateral having a side $2a$ has twice the length of the perimeter of a similar quadrilateral whose corresponding side is a; the circumference of a circle of radius $2r$ is twice that of one of radius r; and so on.

Areas of Similar Figures are to each other as the squares of their respective linear dimensions. Thus, the area of a triangle having a side $2a$ is four times the area of a similar triangle whose corresponding side is a; the area of the surface of a sphere of radius $2r$ is four times the area of one of radius r; and so on.

Volumes of Similar Solids are to each other as the cubes of their respective linear dimensions. Thus, the volume of a right regular pyramid of altitude $2h$ is eight times the volume of a similar pyramid of altitude h; the volume of a sphere of radius $2r$ is eight times the volume of one of radius r; and so on.

Table I. Mensuration Formulas

Approximate Decimal Equivalents (for reference):

$$\pi = 3.1416$$

$$\frac{\pi}{2} = 1.5708$$

$$\frac{\pi}{4} = 0.7854$$

$$\frac{\pi}{180} = 0.01745$$

$$\frac{\pi}{360} = 0.00873$$

$$\frac{1}{\pi} = 0.318$$

$$\frac{1}{2\pi} = 0.159$$

$$\frac{1}{4\pi} = 0.080$$

$$\frac{180}{\pi} = 57.296$$

$$\frac{360}{\pi} = 114.591$$

$$\sqrt{2} = 1.414$$

$$\sqrt{3} = 1.732$$

$$\frac{1}{\sqrt{2}} = 0.707$$

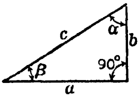
$$\frac{1}{\sqrt{3}} = 0.577$$

Ia. Plane Rectilinear Figures

Notation. Lines, a, b, c, . . . ; angles, α, β, γ, . . . ; altitude (perpendicular height), h; side, s; diagonals, d, d_1, . . . ; perimeter, p; radius of inscribed circle, r; radius of circumscribed circle, R; area, A.

---

1. Right Triangle



(One angle 90°)

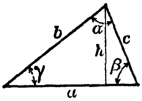
$p = a + b + c$; $c^2 = a^2 + b^2$;

$$A = \frac{ab}{2} = \frac{a^2}{2}\tan\beta = \frac{c^2}{4}\sin 2\beta = \frac{c^2}{4}\sin 2\alpha.$$

For additional formulas, see *General Triangle* below, and also trigonometry.

---

2. General Triangle (and Equilateral Triangle)



For General Triangle:

$p = a + b + c$. Let $s = \frac{1}{2}(a + b + c)$.

$$r = \frac{\sqrt{s(s-a)(s-b)(s-c)}}{s};\quad R = \frac{a}{2\sin\alpha} = \frac{abc}{4rs};$$

$$A = \frac{ah}{2} = \frac{ab}{2}\sin\gamma = \frac{b^2\sin\gamma\sin\alpha}{2\sin\beta} = rs = \frac{abc}{4R}.$$

Length of median to side $c = \frac{1}{2}\sqrt{2(a^2 + b^2) - c^2}$.

Length of bisector of angle $\gamma = \dfrac{\sqrt{ab[(a+b)^2 - c^2]}}{a + b}$.

For Equilateral Triangle ($a = b = c = s$ and $\alpha = \beta = \gamma = 60°$):

(Equal sides and equal angles)

$$p = 3s;\quad r = \frac{s}{2\sqrt{3}};\quad R = \frac{s}{\sqrt{3}} = 2r;$$

$$h = \frac{s\sqrt{3}}{2};\quad s = \frac{2h}{\sqrt{3}};\quad A = \frac{s^2\sqrt{3}}{4}.$$

For additional formulas, see trigonometry.

---

3. Rectangle (and Square)

For Rectangle:

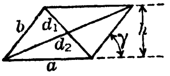
$p = 2(a + b)$; $d = \sqrt{a^2 + b^2}$; $A = ab$.

For Square ($a = b = s$):

$$p = 4s;\quad d = s\sqrt{2};\quad s = \frac{d}{\sqrt{2}};\quad A = s^2 = \frac{d^2}{2}.$$

---

4. General Parallelogram (Rhomboid) (and Rhombus)



For General Parallelogram (Rhomboid):

(Opposite sides parallel)

$p = 2(a + b)$; $d_1 = \sqrt{a^2 + b^2 - 2ab\cos\gamma}$;

$d_2 = \sqrt{a^2 + b^2 + 2ab\cos\gamma}$; $d_1^2 + d_2^2 = 2(a^2 + b^2)$;

$A = ah = ab\sin\gamma$.

For Rhombus ($a = b = s$):

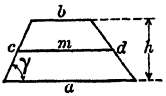
(Opposite sides parallel and all sides equal)

$$p = 4s;\quad d_1 = 2s\sin\frac{\gamma}{2};\quad d_2 = 2s\cos\frac{\gamma}{2};\quad d_1^2 + d_2^2 = 4s^2;$$

$$d_1 d_2 = 2s^2\sin\gamma;\quad A = sh = s^2\sin\gamma = \frac{d_1 d_2}{2}.$$

---

5. General Trapezoid (and Isosceles Trapezoid)



Let mid-line bisecting non-parallel sides $= m$. Then $m = \dfrac{a + b}{2}$.

For General Trapezoid:

(Only one pair of opposite sides parallel)

$$p = a + b + c + d;\quad A = \frac{(a + b)h}{2} = mh.$$

For Isosceles Trapezoid ($d = c$):

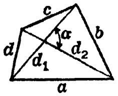
(Non-parallel sides equal)

$$A = \frac{(a + b)h}{2} = mh = \frac{(a + b)c\sin\gamma}{2}$$

$$= (a - c\cos\gamma)c\sin\gamma = (b + c\cos\gamma)c\sin\gamma.$$

Ia. Plane Rectilinear Figures—*Continued*

6. General Quadrilateral (Trapezium)

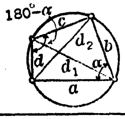


(No sides parallel)

$p = a + b + c + d$

$A = \frac{1}{2} d_1 d_2 \sin \alpha$ = sum of areas of the two triangles formed by either diagonal and the four sides.

7. Quadrilateral Inscribed in Circle



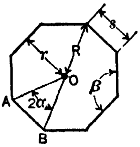
(Sum of opposite angles = 180°)

$ac + bd = d_1 d_2$.

Let $s = \frac{1}{2}(a + b + c + d) = \frac{p}{2}$ and α = angle between sides a and b.

$A = \sqrt{(s - a)(s - b)(s - c)(s - d)} = \frac{1}{2}(ab + cd) \sin \alpha$.

8. Regular Polygon (and General Polygon)



For Regular Polygon:

(Equal sides and equal angles)

Let n = number of sides.

Central angle $= 2\alpha = \frac{2\pi}{n}$ radians;

Vertex angle $= \beta = \frac{(n-2)}{n} \pi$ radians.

$p = ns$; $s = 2r \tan \alpha = 2R \sin \alpha$;

$r = \frac{s}{2} \cot \alpha$; $R = \frac{s}{2} \csc \alpha$;

$A = \frac{nsr}{2} = nr^2 \tan \alpha = \frac{nR^2}{2} \sin 2\alpha = \frac{ns^2}{4} \cot \alpha$ = sum of areas of the n equal triangles such as OAB.

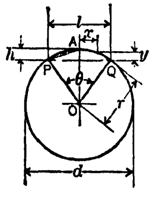
For General Polygon:

A = sum of areas of constituent triangles into which it can be divided.

Ib. Plane Curvilinear Figures

Notation. Lines, a, b, . . . ; radius, r; diameter, d; perimeter, p; circumference, c; central angle in radians, θ; arc, s; chord of arc (s), l; chord of half arc $(s/2)$, l'; rise, h; area, A.

9. Circle (and Circular Arc)



For Circle:

$d = 2r$; $c = 2\pi r = \pi d$; $A = \pi r^2 = \frac{\pi d^2}{4} = \frac{c^2}{4\pi}$.

For Circular Arc:

Let arc $PAQ = s$; and chord $PA = \left(\text{chord of } \frac{s}{2}\right) = l'$. Then,

$s = r\theta = \frac{d\theta}{2}$; $s = \frac{8l' - l}{3}$. (The latter equation is Huyghen's approximate formula. For θ small, error is very small; for $\theta = 120°$, error equals about 1 part in 400; for $\theta = 180°$, error is less than 1.25%.)

$l = 2r \sin \frac{\theta}{2}$; $l = 2\sqrt{2hr - h^2}$ (approximate formula)

$r = \frac{s}{\theta} = \frac{l}{2 \sin \frac{\theta}{2}}$; $r = \frac{4h^2 + l^2}{8h}$ (approximate formula)

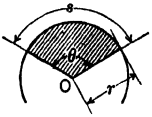
$$h = r \mp \sqrt{r^2 - \frac{l^2}{4}} \;(- \text{ if } \theta \leqq 180°;\; + \text{ if } \theta \geqq 180°) = r\left(1 - \cos \frac{\theta}{2}\right)$$

$$= r \operatorname{versin} \frac{\theta}{2} = 2r \sin^2 \frac{\theta}{4} = \frac{l}{2} \tan \frac{\theta}{4} = r + y - \sqrt{r^2 - x^2}.$$

Side ordinate $y = h - r + \sqrt{r^2 - x^2}$.

Ib. Plane Curvilinear Figures—*Continued*

10. Circular Sector (and Semicircle)



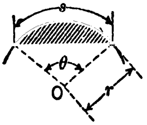
For Circular Sector:

$$A = \frac{\theta r^2}{2} = \frac{sr}{2}.$$

For Semicircle:

$$A = \frac{\pi r^2}{2}.$$

11. Circular Segment

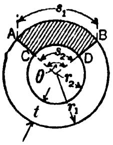


$$A = \frac{r^2}{2}(\theta - \sin\theta)$$

$$= 1/2\,[sr \mp l\,(r - h)]\ (-\text{ if } h \leqq r;\ +\text{ if } h \geqq r).$$

$$A = \frac{2lh}{3} \text{ or } \frac{h}{15}(8l' + 6l).$$ (Approximate formulas. For h small compared with r, error is very small; for $h = \frac{r}{4}$, first formula errs about 3.5% and second less than 1.0%.)

12. Annulus



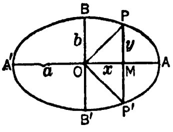
(Surface between two concentric circles)

$$A = \pi(r_1^2 - r_2^2) = \pi(r_1 + r_2)(r_1 - r_2);$$

$$A \text{ of sector } ABCD = \frac{\theta}{2}(r_1^2 - r_2^2) = \frac{\theta}{2}(r_1 + r_2)(r_1 - r_2)$$

$$= \frac{t}{2}(s_1 + s_2).$$

13. Ellipse



$$p = \pi\,(a + b)\left(1 + \frac{R^2}{4} + \frac{R^4}{64} + \frac{R^6}{256} + \ldots\right) \text{ where } R = \frac{a - b}{a + b}.$$

$$p = \pi\,(a + b)\,\frac{64 - 3\,R^4}{64 - 16\,R^2} \text{ (approximate formula).}$$

$$A = \pi\,ab;\ A \text{ of quadrant } AOB = \frac{\pi\,ab}{4};$$

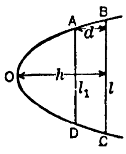
$$A \text{ of sector } AOP = \frac{ab}{2}\cos^{-1}\frac{x}{a};\ A \text{ of sector } POB = \frac{ab}{2}\sin^{-1}\frac{x}{a};$$

$$A \text{ of section } BPP'B' = xy + ab\sin^{-1}\frac{x}{a};$$

$$A \text{ of segment } PAP'P = -\,xy + ab\cos^{-1}\frac{x}{a}.$$

For additional formulas, see analytic geometry.

14. Parabola



$$\text{Arc } BOC = s = 1/2\sqrt{l^2 + 16\,h^2} + \frac{l^2}{8h}\log_e\frac{4\,h + \sqrt{l^2 + 16\,h^2}}{l}.$$

Let $R = \frac{h}{l}$. Then,

$$s = l\,(1 + \frac{8\,R^2}{3} - \frac{32\,R^4}{5} + \ldots) \text{ (approximate formula).}$$

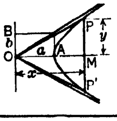
$$d = \frac{h}{l^2}(l^2 - l_1^2);\ l_1 = l\sqrt{\frac{h - d}{h}};\ h = \frac{dl^2}{l^2 - l_1^2};$$

$$A \text{ of segment } BOC = \frac{2\,hl}{3};$$

$$A \text{ of section } ABCD = \frac{2}{3}\,d\left(\frac{l^3 - l_1^3}{l^2 - l_1^2}\right).$$

For additional formulas, see analytic geometry.

15. Hyperbola



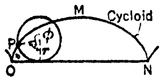
$$A \text{ of figure } OPAP'O = ab\log_e\left(\frac{x}{a} + \frac{y}{b}\right) = ab\cosh^{-1}\frac{x}{a};$$

$$A \text{ of segment } PAP' = xy - ab\log_e\left(\frac{x}{a} + \frac{y}{b}\right) = xy - ab\cosh^{-1}\frac{x}{a}.$$

For additional formulas, see analytic geometry.

Ib. Plane Curvilinear Figures—*Continued*

16. Cycloid

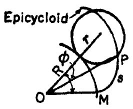


Arc $OP = s = 4r\left(1 - \cos\frac{\phi}{2}\right)$; Arc $OMN = 8r$;

A under curve $OMN = 3\pi r^2$.

For additional formulas, see analytic geometry.

17. Epicycloid

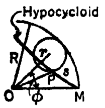


Arc $MP = s = \frac{4r}{R}(R + r)\left(1 - \cos\frac{R\phi}{2r}\right)$;

Area $MOP = A = \frac{r}{2R}(R + r)(R + 2r)\left(\frac{R\phi}{r} - \sin\frac{R\phi}{r}\right)$.

For additional formulas, see analytic geometry.

18. Hypocycloid

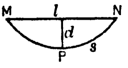


Arc $MP = s = \frac{4r}{R}(R - r)\left(1 - \cos\frac{R\phi}{2r}\right)$;

Area $MOP = A = \frac{r}{2R}(R - r)(R - 2r)\left(\frac{R\phi}{r} - \sin\frac{R\phi}{r}\right)$.

For additional formulas, see analytic geometry.

19. Catenary

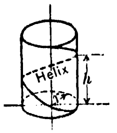


If d is small compared with l:

Arc $MPN = s = l\left[1 + \frac{2}{3}\left(\frac{2d}{l}\right)^2\right]$ (approximately).

For additional formulas, see analytic geometry.

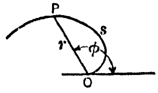
20. Helix



Let length of helix $= s$; radius of coil (= radius of cylinder in figure) $= r$; distance advanced in one revolution = pitch $= h$; and number of revolutions $= n$. Then,

$s = n\sqrt{(2\pi r)^2 + h^2}$.

21. Spiral of Archimedes

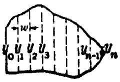


Let $a = \frac{r}{\phi}$. Then,

Arc $OP = s = \frac{a}{2}\left[\phi\sqrt{1 + \phi^2} + \log_e\left(\phi + \sqrt{1 + \phi^2}\right)\right]$.

For additional formulas, see analytic geometry.

22. Irregular Figure



Divide the figure into an *even* number, n, of strips by means of $(n + 1)$ ordinates, y_i, spaced equal distances, w. The area can then be determined approximately by any of the following formulas, which are presented in the order of usual increasing approach to accuracy. In any of the first three cases, the greater the number of strips used, the more nearly accurate will be the result.

(Approximate Formulas)

Trapezoidal Rule. . . . .

$$A = w\left[\frac{y_0 + y_n}{2} + y_1 + y_2 + \dots + y_{n-1}\right];$$

Durand's Rule. . . . .

$$A = w\left[0.4(y_0 + y_n) + 1.1(y_1 + y_{n-1}) + y_2 + y_3 + \dots + y_{n-2}\right];$$

Simpson's Rule. . . . .
(*n must* be even)

$$A = \frac{w}{3}\left[(y_0 + y_n) + 4(y_1 + y_3 + \dots + y_{n-1}) + 2(y_2 + y_4 + \dots + y_{n-2})\right];$$

Weddle's Rule. . . . .
(for 6 strips only)

$$A = \frac{3w}{10}\left[5(y_1 + y_5) + 6y_3 + y_0 + y_2 + y_4 + y_6\right].$$

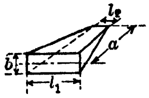
Areas of irregular surfaces can often be determined more quickly by such methods as plotting on squared paper and counting the squares; graphical coordinate representation (see analytic geometry); or use of a planimeter.

Ic. Solids Having Plane Surfaces

Notation. Lines, a, b, c, . . . ; altitude (perpendicular height), h; slant height, s; perimeter of base, p_b or p_B; perimeter of a right section, p_r; area of base, A_b or A_B; area of a right section, A_r; total area of lateral surfaces, A_l; total area of all surfaces, A_t; volume, V.

---

23. Wedge (and Right Triangular Prism)



For Wedge:

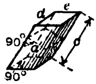
(Narrow-side rectangular); $V = \frac{ab}{6}(2l_1 + l_2)$.

For Right Triangular Prism (or wedge having parallel triangular bases perpendicular to sides) $l_2 = l_1 = l$:

$$V = \frac{abl}{2}.$$

---

24. Rectangular Prism (or Rectangular Parallelepiped) (and Cube)



For Rectangular Prism or Rectangular Parallelepiped:

$A_l = 2c(a + b)$; $A_t = 2(de + ac + bc)$;

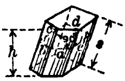
$V = A_r c = abc$.

For Cube (letting $b = c = a$):

$A_t = 6a^2$; $V = a^3$; Diagonal $= a\sqrt{3}$.

---

25. General Prism

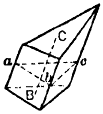


$A_l = hp_b = sp_r = s(a + b + \ldots + n)$;

$V = hA_b = sA_r$.

---

26. General Truncated Prism (and Truncated Triangular Prism)



For General Truncated Prism:

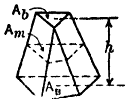
$V = A_r \cdot$(length of line BC joining centers of gravity of bases).

For Truncated Triangular Prism:

$$V = \frac{A_r}{3}(a + b + c).$$

---

27. Prismatoid

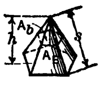


Let area of mid-section $= A_m$.

$$V = \frac{h}{6}(A_B + A_b + 4A_m).$$

---

28. Right Regular Pyramid (and Frustum of Right Regular Pyramid)



For Right Regular Pyramid:

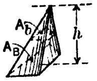
$A_l = \frac{sp_B}{2}$; $V = \frac{hA_B}{3}$.

For Frustum of Right Regular Pyramid:

$A_l = \frac{s}{2}(p_B + p_b)$; $V = \frac{h}{3}\left(A_B + A_b + \sqrt{A_B A_b}\right)$.

---

29. General Pyramid (and Frustum of Pyramid)



For General Pyramid:

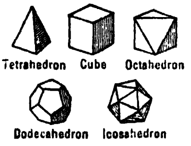
$$V = \frac{hA_B}{3}.$$

For Frustum of General Pyramid:

$$V = \frac{h}{3}\left(A_B + A_b + \sqrt{A_B A_b}\right).$$

---

30. Regular Polyhedrons



Let edge $= a$, and radius of inscribed sphere $= r$. Then,

$r = \frac{3V}{A_t}$, and:

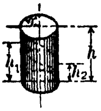
Number of Faces	*Form of Faces*	*Total Area A_t*	*Volume V*
4	Equilateral triangle	1.7321 a^2	0.1179 a^3
6	Square	6.0000 a^2	1.0000 a^3
8	Equilateral triangle	3.4641 a^2	0.4714 a^3
12	Regular pentagon	20.6457 a^2	7.6631 a^3
20	Equilateral triangle	8.6603 a^2	2.1817 a^3

(Factors shown only to four decimal places.)

Id. Solids Having Curved Surfaces

Notation. Lines, a, b, c, . . . ; altitude (perpendicular height), h, h_1, . . . ; slant height, s; radius, r; perimeter of base, p_b; perimeter of a right section, p_r; angle in radians, ϕ; arc, s; chord of segment, l; rise, h; area of base, A_b or A_B; area of a right section, A_r; total area of convex surface, A_l; total area of all surfaces, A_t; volume, V.

31. Right Circular Cylinder (and Truncated Right Circular Cylinder)



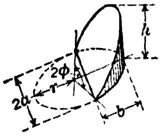
For Right Circular Cylinder:

$$A_l = 2\pi rh;\ A_t = 2\pi r\,(r + h);$$
$$V = \pi r^2 h.$$

For Truncated Right Circular Cylinder:

$$A_l = \pi r\,(h_1 + h_2);\ A_t = \pi r\left[h_1 + h_2 + r + \sqrt{r^2 + \left(\frac{h_1 - h_2}{2}\right)^2}\right];$$
$$V = \frac{\pi r^2}{2}\,(h_1 + h_2).$$

32. Ungula (Wedge) of Right Circular Cylinder

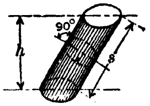


$$A_l = \frac{2\,rh}{b}\,[a + (b - r)\phi];$$
$$V = \frac{h}{3b}\,[a\,(3r^2 - a^2) + 3\,r^2\,(b - r)\phi]$$
$$= \frac{hr^3}{b}\left[\sin\phi - \frac{\sin^3\phi}{3} - \phi\cos\phi\right].$$

For Semicircular Base (letting $a = b = r$):

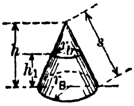
$$A_l = 2\,rh;\ V = \frac{2\,r^2h}{3}.$$

33. General Cylinder



$$A_l = p_b h = p_r s;$$
$$V = A_b h = A_r s.$$

34. Right Circular Cone (and Frustum of Right Circular Cone)



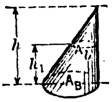
For Right Circular Cone:

$$A_l = \pi r_B s = \pi r_B\sqrt{r_B{}^2 + h^2};\ A_t = \pi r_B\,(r_B + s);$$
$$V = \frac{\pi r_B{}^2 h}{3}.$$

For Frustum of Right Circular Cone:

$$s = \sqrt{h_1{}^2 + (r_B - r_b)^2};\ A_l = \pi s\,(r_B + r_b);$$
$$V = \frac{\pi h_1}{3}\,(r_B{}^2 + r_b{}^2 + r_B r_b).$$

35. General Cone (and Frustum of General Cone)



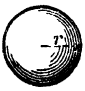
For General Cone:

$$V = \frac{A_B h}{3}.$$

For Frustum of General Cone:

$$V = \frac{h_1}{3}\left(A_B + A_b + \sqrt{A_B A_b}\right).$$

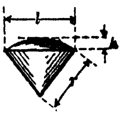
36. Sphere



Let diameter $= d$.

$$A_t = 4\pi r^2 = \pi d^2;$$
$$V = \frac{4\pi r^3}{3} = \frac{\pi d^3}{6}.$$

37. Spherical Sector (and Hemisphere)



For Spherical Sector:

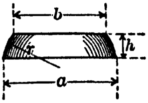
$$A_t = \frac{\pi r}{2}\,(4h + l);\ V = \frac{2\pi r^2 h}{3}.$$

For Hemisphere (letting $h = \frac{l}{2} = r$):

$$A_t = 3\pi r^2;\ V = \frac{2\pi r^3}{3}.$$

Id. Solids Having Curved Surfaces—*Continued*

38. Spherical Zone (and Spherical Segment)



For Spherical Zone Bounded by Two Planes:

$$A_l = 2\pi rh;\quad A_t = \frac{\pi}{4}(8\,rh + a^2 + b^2).$$

For Spherical Zone Bounded by One Plane ($b = 0$):

$$A_l = 2\pi rh = \frac{\pi}{4}(4\,h^2 + a^2);$$

$$A_t = \frac{\pi}{4}(8\,rh + a^2) = \frac{\pi}{2}(2\,h^2 + a^2).$$

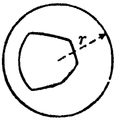
For Spherical Segment with Two Bases:

$$V = \frac{\pi h}{24}(3\,a^2 + 3\,b^2 + 4\,h^2).$$

For Spherical Segment with One Base ($b = 0$):

$$V = \frac{\pi h}{24}(3\,a^2 + 4\,h^2) = \pi h^2\left(r - \frac{h}{3}\right).$$

39. Spherical Polygon (and Spherical Triangle)



For Spherical Polygon:

Let sum of angles in radians = θ and number of sides = n.

$$A = [\theta - (n - 2)\pi]r^2$$

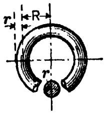
(The quantity $[\theta - (n - 2)\pi]$ is called "spherical excess.")

For Spherical Triangle ($n = 3$):

$$A = (\theta - \pi)\,r^2$$

For additional formulas, see trigonometry.

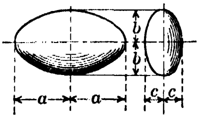
40. Torus



$$A_l = 4\pi^2 Rr;$$

$$V = 2\pi^2 Rr^2.$$

41. Ellipsoid (and Spheroids)



For Ellipsoid:

$$V = \frac{4}{3}\pi abc.$$

For Prolate Spheroid:

Let $c = b$ and $\dfrac{\sqrt{a^2 - b^2}}{a} = e$.

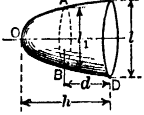
$$A_t = 2\pi b^2 + 2\pi ab\frac{\sin^{-1} e}{e};\quad V = \frac{4}{3}\pi ab^2.$$

For Oblate Spheroid:

Let $c = a$ and $\dfrac{\sqrt{a^2 - b^2}}{a} = e$.

$$A_t = 2\pi a^2 + \frac{\pi b^2}{e}\ln\left(\frac{1+e}{1-e}\right);\quad V = \frac{4}{3}\pi a^2 b.$$

42. Paraboloid of Revolution



$$A_l \text{ of segment } DOC = \frac{2\pi l}{3h^2}\left[\left(\frac{l^2}{16} + h^2\right)^{3/2} - \left(\frac{l}{4}\right)^3\right].$$

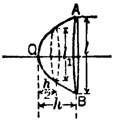
For Paraboloidal Segment with Two Bases:

$$V \text{ of } ABCD = \frac{\pi d}{8}(l^2 + l_1^2).$$

For Paraboloidal Segment with One Base ($l_1 = 0$ and $d = h$):

$$V \text{ of } DOC = \frac{\pi h l^2}{8}.$$

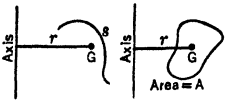
43. Hyperboloid of Revolution



$$V \text{ of segment } AOB = \frac{\pi h}{24}(l^2 + 4l_1^2).$$

Id. Solids Having Curved Surfaces—*Continued*

44. Surface and Solid of Revolution



Let perpendicular distance from axis to center of gravity (G) of curve (or surface) $= r$. Curve (or surface) must not cross axis. Then,

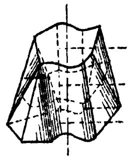
Area of Surface generated by curve revolving about axis:

$$A_l = 2\pi rs.$$

Volume of Solid generated by surface revolving about axis:

$$V = 2\pi rA.$$

45. Irregular Solid



One of the following methods can often be employed to determine the volume of an irregular solid with a reasonable approach to accuracy:

(*a*) Divide the solid into prisms, cylinders, etc., and sum their individual volumes.

(*b*) Divide one surface into triangles, after replacing curved lines by straight ones and curved surfaces by plane ones. Then multiply the area of each triangle by the mean depth of the section beneath it (which generally approximates the average of the depths at its corners). Sum the volumes thus obtained.

(*c*) If two surfaces are parallel, replace any curved lateral surfaces by plane surfaces best suited to the contour and then employ the prismatoidal formula.

23. CONSTRUCTIONS

Typical Constructions applicable to the graphical solution of common elementary geometrical problems are presented in the following paragraphs. If two or more methods of solution are possible but almost equally simple under all circumstances, only one method, in general, is given.

Lines

1. To draw a line parallel to a given line.

Case 1. At a given distance from the given line (Fig. 15*a*).

With the given distance as radius and with any centers *m* and *n* on the given line *AB*, describe arcs *xy* and *zw*, respectively. Draw *CD* touching these arcs. *CD* is the required parallel line.

Case 2. Through a given point (Fig. 15*b*). Let *C* be the given point and *D* be any point on the given line *AB*. Draw *CD*. With equal radii draw arcs *bf* and *ce* with *D* and *C*, respectively, as centers. With radius equal to chord *bf* and with *c* as center draw an arc cutting arc *ce* at *E*. *CE* is the required parallel line.

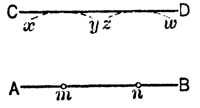


Fig. 15*a*

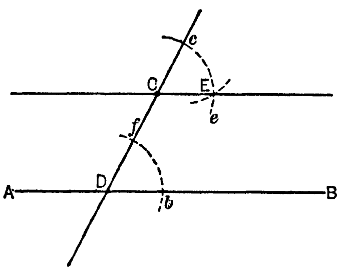

Fig. 15*b*

2. To bisect a given line (Fig. 16). Let *AB* be the given line. With any radius greater than 0.5 *AB* describe two arcs with *A* and *B* as centers. The line *CD*, through points of intersection of the arcs, is the perpendicular bisector of the given line.

3. To divide a given line into a given number of equal parts (Fig. 17). Let *AB* be the given line and let the number of equal parts be five. Draw line *AC* at any convenient angle with *AB*, and step off with dividers five equal lengths from *A* to *b*. Connect *b* with *B*, and draw parallels to *Bb* through the other points in *AC*. The intersections of these parallels with *AB* determine the required equal parts on the given line.

4. To divide a given line into segments proportional to a number of given unequal parts. Follow the same procedure as under 3 above except make the lengths on *AC* equal to (or proportional to) the lengths of the given unequal parts.

5. To erect a perpendicular to a given line at a given point in the line.

Case 1. Point *C* is at or near the middle of the line *AB* (Fig. 18). With *C* as center, describe arcs of equal radii intersecting *AB* at *a* and *b*. With *a* and *b* as centers, and any radius greater than *Ca*, describe arcs intersecting at *D*. *CD* is the required perpendicular.

Case 2. Point C is at or near the extremity of the line AB (Fig. 19). With any point O, as center, and radius OC, describe an arc intersecting AB at a. Extend aO to intersect the arc at D. CD is the required perpendicular.

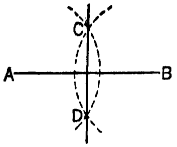

FIG. 16

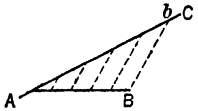

FIG. 17

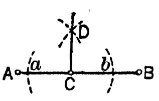

FIG. 18

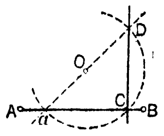

FIG. 19

6. To erect a perpendicular to a given line through a given point outside the line.

Case 1. Point C is opposite, or nearly opposite, the middle of the line AB (Fig. 20). With C as center, describe an arc intersecting AB at a and b. With a and b as centers, describe arcs of equal radii intersecting at D. CD is the required perpendicular.

Case 2. Point C is opposite, or nearly opposite, the extremity of the line AB (Fig. 21). Through C, draw any line intersecting AB at a. Divide line Ca into two equal parts, ab and bC (method given above). With b as center, and radius bC, describe an arc intersecting AB at D. CD is the required perpendicular.

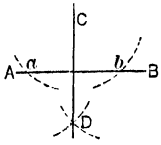

FIG. 20

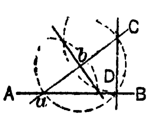

FIG. 21

Angles

7. To bisect a given angle.

Case 1. Vertex B is accessible (Fig. 22). Let ABC be the given angle. With B as center, and a large radius, describe an arc intersecting AB and BC at a and c respectively. With a and c as centers, describe arcs of equal radii intersecting at D. DB is the required bisector.

Case 2. The vertex is inaccessible (Fig. 23). Let the given angle be that between lines AB and BC. Draw lines ab and bc parallel to the given lines, and at equal distances from them, intersecting at b. Construct Db bisecting angle abc (method given above). Db is the required bisector.

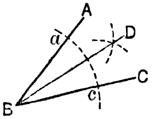

FIG. 22

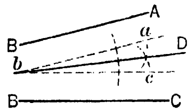

FIG. 23

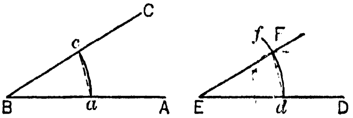

FIG. 24

8. To construct an angle equal to a given angle if one new side and the new vertex are given (Fig. 24). Let ABC be the given angle; DE the new side; and E the new vertex. With center B and a convenient radius, describe arc ac. With the same radius and center E, draw arc df. With radius equal to chord ac and with center d draw an arc cutting the arc df at F. Draw EF. Then DEF is the required angle.

9. To construct angles of 60° and 30° (Fig. 25). About any point A on a line AB, describe with a convenient radius the arc bc. From b, using an equal radius, describe an arc cutting the former one at C. Draw AC, and drop a perpendicular CD from C to line AB. Then CAD is a 60° angle and ACD is a 30° angle.

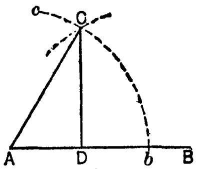

FIG. 25

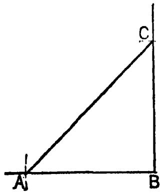

FIG. 26

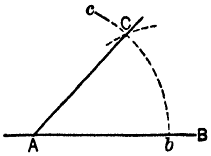

FIG. 27

10. To construct an angle of 45° (Fig. 26). Set off any distance AB; draw BC perpendicular and equal to AB; and join CA. Angles CAB and ACB are each 45°.

11. To draw a line making a given angle with a given line (Fig. 27). Let *AB* be the given line. With *A* as the center and with as large a radius as convenient, describe arc *bc*. Determine from Table 9, Section 1, the length of chord to radius one, corresponding to the given angle. Multiply this chord by the length of *Ab*, and with the product as a new radius and *b* as a center, describe an arc cutting *bc* at *C*. Draw *AC*. This line makes the required angle with *AB*.

Circles

12. To describe through two given points an arc of a circle having a given radius (Fig. 28). Let *A* and *B* be the given points. With the given radius, and these points as centers, describe arcs cutting each other at *C*. From *C*, with the same radius, describe arc *AB*, which is the required arc.

13. To bisect a given arc of a circle. Draw the perpendicular bisector of the chord of the arc. The point in which this bisector meets the arc is the required mid-point.

14. To locate the center of a given circle or circular arc (Fig. 29). Select three points, *A*, *B*, *C*, on the circle (or arc), located well apart. Draw chords *AB* and *BC* and erect their perpendicular bisectors. The point *O*, where the bisectors intersect, is the required center.

15. To draw a circle through three given points not in the same straight line.

Case 1. Radius small and center accessible (Fig. 29). Let *A*, *B*, *C*, be the given points. Draw lines *AB* and *BC* and erect their perpendicular bisectors. From point *O*, where the bisectors intersect, describe a circle of radius *OA* which is the required circle.

Case 2. Radius very long or center inaccessible (Fig. 30). Let *A*, *O*, *A'*, be the given points (*O* not necessarily mid-point of *AOA'*). Draw arcs *Aa'* and *A'a* with centers at *A'* and *A* respectively; extend *AO* to determine *a* and *A'O* to determine *a'*; point off from *a* on *aA'* equal parts *ab*, *bc*, etc.; lay off *a'b'*, *b'c'*, etc., equal to *ab*; join *A* with any point as *b* and *A'* with the corresponding point *b'*; the intersection *P* of these joining lines is a point on the required circle.

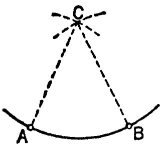

Fig. 28

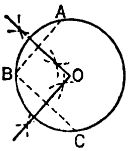

Fig. 29

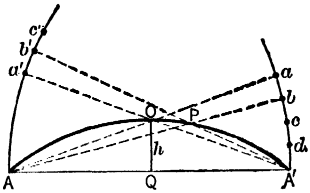

Fig. 30

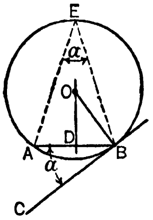

Fig. 31

16. To lay out a circular arc without locating the center of the circle, having given the chord and the rise (Fig. 30). Let *AA'* be the chord and *QO* the rise. (In this case, *O* is mid-point of *AOA'*.) The arc can be constructed through the points *A*, *O*, *A'*, as under 15, Case 2, above.

17. To construct, upon a given chord, a circle in which a given angle can be inscribed (Fig. 31). Let *AB* be the given line, and α the given angle. Construct angle *ABC* equal to angle α. Bisect line *AB* by the perpendicular at *D*. Draw a perpendicular to *BC* from point *B*. With *O*, the point of intersection of the perpendiculars, as center, and *OB* as radius, describe a circle. The angle *AEB*, with vertex *E* located anywhere on the arc *AEB*, equals α, and therefore the circle just drawn is the one required.

18. To draw a tangent to a given circle through a given point.

Case 1. Point *A* is on the circle (Fig. 32). Draw radius *OA*. Through *A*, perpendicular to *OA*, draw *BAC*, the required tangent.

Case 2. Point *A* is outside the circle (Fig. 33). Two tangents can be drawn. Join *O* and *A*. Bisect *OA* at *D*, and with *D* as center and *DO* as radius, describe an arc intersecting the given circle at *B* and *C*. *BA* and *CA* are the required tangents.

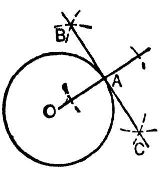

Fig. 32

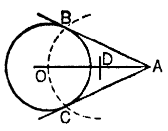

Fig. 33

19. To draw a common tangent to two given circles. Let the circles have centers *O* and *O'* and corresponding radii *r* and *r'* ($r > r'$).

Case 1. Common internal tangents (when circles do not intersect) (Fig. 34). Construct a circle having the same center *O* as the larger circle and a radius equal to the sum of the radii of the given circles ($r + r'$). Construct a tangent *O'P* from center *O'* of the smaller circle to this circle. Construct *O'N* perpendicular to this tangent. Draw *OP*. The line *MN* joining the extremities of the radii *OM* and *O'N* is a common tangent. The figure shows two such common internal tangents.

Case 2. Common external tangents (Fig. 35). Construct a circle having the same center *O* as the larger circle and radius equal to the difference of the radii ($r - r'$). Construct a tangent to this circle from the center of the smaller circle. The line joining the extremities *M*, *N*, of the radii of the given circles perpendicular to this tangent is a required common tangent. There are two such tangents.

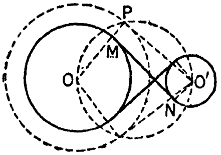

Fig. 34

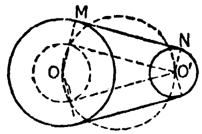

Fig. 35

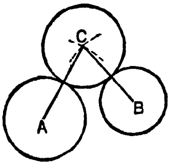

Fig. 36

20. To draw a circle with a given radius that will be tangent to two given circles (Fig. 36). Let *R* be the given radius and *A* and *B* the given circles. About center of circle *A* with radius equal to *R* plus radius of *A*, and about center of *B* with radius equal to *R* plus radius of *B*, draw two arcs cutting each other in *C*, which is the center of the required circle.

21. To describe a circular arc touching two given circles, one of them at a given point (Fig. 37). Let *AB*, *FG* be the given circles and *F* the given point. Draw the radius *EF*, and produce it both ways. Set off *FH* equal to the radius *AC* of the other circle; join *CH*, and bisect it by the perpendicular *LT*, cutting *EF* at *T*. About center *T*, with radius *TF*, describe arc *FA* as required.

22. To draw a circular arc that will be tangent to two given lines inclined to one another, one tangential point being given (Fig. 38). Let *AB* and *CD* be the given lines and *E* the given point. Draw the line *GH*, bisecting the angle formed by *AB* and *CD*. From *E* draw *EF* at right angles to *AB*; then *F*, its intersection with *GH*, is the center of the required circular arc.

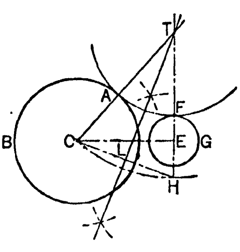

Fig. 37

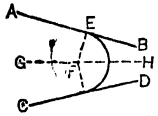

Fig. 38

23. To connect two given parallel lines by a reversed curve composed of two circular arcs of equal radius, the curve being tangent to the lines at given points (Fig. 39). Let *AD* and *BE* be the given lines and *A* and *B* the given points. Join *A* and *B*, and bisect the connecting line at *C*. Bisect *CA* and *CB* by perpendiculars. At *A* and *B* erect perpendiculars to the given lines, and the intersections *a* and *b* are the centers of the arcs composing the required curve.

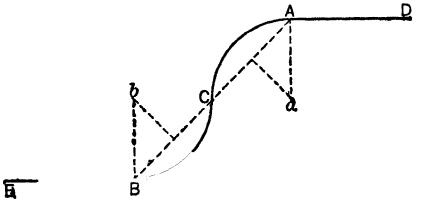

Fig. 39

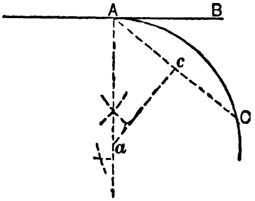

Fig. 40

24. To describe a circular arc which will be tangent to a given line at a given point, and pass through another given point outside the line (Fig. 40). Let *AB* be the given line, *A* the given point on the line, and *C* the given point outside it. Draw from *A* a line perpendicular to the given line. Connect *A* and *C* by a straight line, and bisect this line by the perpendicular *ca*. The point *a* where these two perpendiculars intersect is the center of the required circular arc.

25. To draw a circular arc joining two given relatively inclined lines, tangent to the lines, and passing through a given point on the line bisecting their included angle (Fig. 41). Let *AB* and *DE* be the given lines and *F* the given point on the line *FC* which bisects their included angle. Through *F* draw *DA* at right angles to *FC*; bisect the angles *A* and *D* by lines intersecting at *C*, and about *C* as a center, with radius *CF*, draw the arc *HFG* required.

26. To draw a series of circles between two given relatively inclined lines, touching the lines, and touching each other (Fig. 42). Let *AB* and *CD* be the given lines. Bisect their included angle by the line *NO*. From a point *P* in this line draw the perpendicular *PB* to the line *AB*, and on *P* describe the circle *BD*, touching the given lines and cutting the center line at *E*. From *E* draw *EF* perpendicular to the center line, cutting *AB* at *F*; and about *F* as a center describe an arc *EG*, cutting *AB* at *G*. Draw *GH* parallel to *BP*, giving *H*, the center of the next circle, to be described with the radius *HE*; and so on for the next circle *IN*.

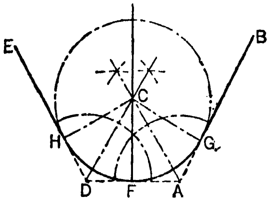

Fig. 41

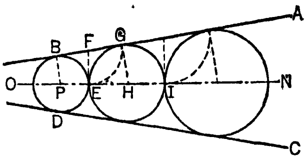

Fig. 42

27. To circumscribe a circle about a given triangle (Fig. 43). Construct perpendicular bisectors of two sides. Their point of intersection *O* is the center (*circumcenter*) of the required circle.

28. To inscribe a circle in a given triangle (Fig. 44). Draw bisectors of two angles, intersecting in *O* (*incenter*). From *O* draw *OD* perpendicular to *BC*. Then the circle with center *O* and radius *OD* is the required circle.

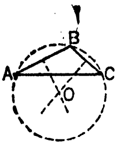

Fig. 43

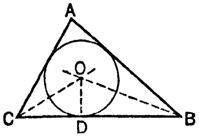

Fig. 44

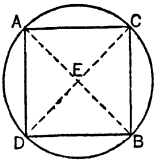

Fig. 45

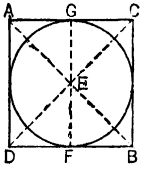

Fig. 46

29. To circumscribe a circle about a given square (Fig. 45). Let *ACBD* be the given square. Draw diagonals *AB* and *CD* of the square, intersecting at *E*. On center *E*, with radius *AE*, describe the required circle. The same procedure can be used for circumscribing a circle about a given rectangle.

30. To inscribe a circle in a given square (Fig. 46). Let *ACBD* be the given square. Draw diagonals *AB* and *CD* of the square, intersecting at *E*. Drop a perpendicular *EF* from *E* to one side. On center *E*, with radius *EF*, describe the required circle.

31. To circumscribe a circle about a given regular polygon.

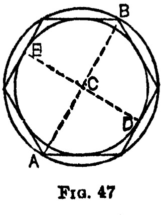

Fig. 47

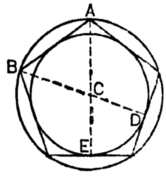

Fig. 48

Case 1. The polygon has an even number of sides (Fig. 47). Draw a diagonal *AB* joining two opposite vertices. Bisect the diagonal by a perpendicular line *DE*, which is another diagonal or a line bisecting two opposite sides, depending upon whether the number of sides is, or is not, divisible by 4. With the midpoint *C* as the center, and radius *CA*, describe the required circle.

Case 2. The polygon has an odd number of sides (Fig. 48). Bisect two of the sides at *D* and *E* by the perpendicular lines *DB* and *EA* which pass through the respective opposite vertices and intersect at a point *C*. With *C* as the center, and radius *CA*, describe the required circle.

32. To inscribe a circle in a given regular polygon (Figs. 47, 48). Locate the center, *C*, as in 31 above. With *C* as center, and radius *CD*, describe the required circle.

Polygons

33. To construct a triangle on a given base, the lengths of the sides being given (Fig. 49). Let *AB* be the given base and *a*, *b*, the given lengths of sides. With *A* and *B* as centers, and *b* and *a* as respective radii, describe arcs intersecting at *C*. Draw *AC* and *BC* to complete the required triangle.

34. To construct a rectangle of given base and given height (Fig. 50). Let *AB* be the base and *c* the height. Erect the perpendicular *AC* equal to *c*. With *C* and *B* as centers, and *AB* and *c* as respective radii, describe arcs intersecting at *D*. Draw *BD* and *CD* to complete the required rectangle.

35. To construct a square with a given diagonal (Fig. 51). Let *AC* be the given diagonal. Draw a circle on *AC* as diameter and erect the diameter *BD* perpendicular to *AC*. Then *ABCD* is the required square.

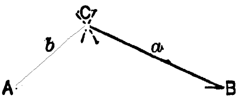

FIG. 49

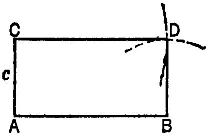

FIG. 50

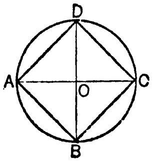

FIG. 51

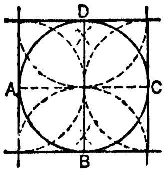

FIG. 52

36. To inscribe a square in a given circle (Fig. 51). Draw perpendicular diameters *AC* and *BD*. Their extremities are the vertices of an inscribed square.

37. To circumscribe a square about a given circle (Fig. 52). Draw perpendicular diameters *AC* and *BD*. With *A*, *B*, *C*, *D*, as centers, and the radius of the circle as radius, describe the four semicircular arcs shown. Their outer intersections are the vertices of the required square.

38. To inscribe a regular pentagon in a given circle (Fig. 53). Draw perpendicular diameters *AC* and *BD* intersecting at *O*. Bisect *AO* at *E* and with *E* as center, and *EB* as radius, draw an arc cutting *AC* at *F*. With *B* as center and *BF* as radius, draw an arc cutting the circle at *G* and *H*; also with the same radius, step around the circle to *I* and *K*. Join the points thus found to form the pentagon.

39. To inscribe a regular hexagon in a given circle (Fig. 54). Step around the circle with compasses set to the radius and join consecutive divisions thus marked off.

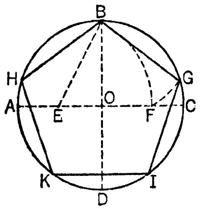

FIG. 53

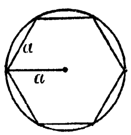

FIG. 54

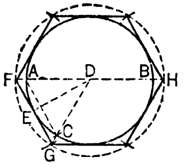

FIG. 55

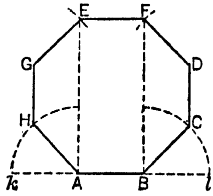

FIG. 56

40. To circumscribe a regular hexagon about a given circle (Fig. 55). Draw a diameter *ADB* and with center *A* and radius *AD*, describe an arc cutting the circle at *C*. Draw *AC* and bisect it with the radius *DE*. Through *E*, draw *FG* parallel to *AC*, cutting diameter *AB* extended at *F*. With center *D* and radius *DF*, describe the circumscribing circle *FH*; and within this circle inscribe a regular hexagon as under 39 above. This hexagon circumscribes the given circle, as required.

41. To construct a regular hexagon having a side of given length (Fig. 54). Draw a circle with radius equal to the given length of side and inscribe a regular hexagon (see 39 above).

42. To construct a regular octagon having a side of given length (Fig. 56). Let *AB* be the given side. Produce *AB* in both directions, and draw perpendiculars *AE* and *BF*.

Bisect the external angles at *A* and *B* by the lines *A H* and *BC*, making them equal to *AB*. Draw *CD* and *HG* parallel to *AE*, and equal to *AB*; from the centers *G*, *D*, with the radius *AB*, draw arcs cutting the perpendiculars at *E*, *F*, and draw *EF* to complete the octagon.

43. To inscribe a regular octagon in a given circle (Fig. 57). Draw perpendicular diameters *AC* and *BD*. Bisect arcs *AB*, *BC*, etc., and join *Ae*, *eB*, etc., to form the octagon.

44. To inscribe a regular octagon in a given square (Fig. 58). Draw diagonals of the given square, intersecting at *O*. With *A*, *B*, *C*, *D*, as centers, and *AO* as radius, describe arcs cutting the sides of the square at *gn*, *fk*, *hm*, and *ol*. Join the points thus found to form the octagon.

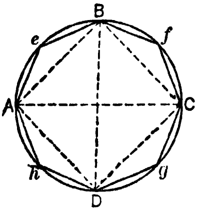

Fig. 57

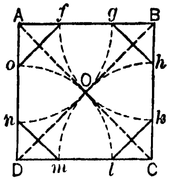

Fig. 58

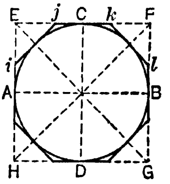

Fig. 59

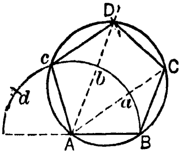

Fig. 60

45. To circumscribe a regular octagon about a given circle (Fig. 59). Describe a square about the given circle. Draw perpendiculars *ij*, *kl*, etc., to the diagonals of the squares, touching the circle. Then *ij*, *jk*, *kl*, etc., form the octagon.

46. To describe a regular polygon of any given number of sides when one side is given (Fig. 60). Let *AB* be the given side and let the number of sides be five. Produce the line *AB*, and with *A* as center and *AB* as radius, describe a semicircle. Divide this into as many equal parts as there are to be sides of the polygon—in this case, five. Draw lines from *A* through the division points *a*, *b*, and *c* (omitting the last). With *B* and *c* as centers, and *AB* as radius, cut *Aa* at *C* and *Ab* at *D*. Draw *cD*, *DC*, and *CB*, to complete the polygon.

47. To inscribe a regular polygon of a given number of sides in a given circle. Determine the central angle subtended by any side by dividing 360° by the number of sides (see Table II). Lay off this angle successively round the center of the circle by means of a protractor. The radii thus drawn intersect the circle at vertices of the required polygon.

Table II. Table of Polygonal Angles

Number of Sides	Angle at Center in Degrees	Number of Sides	Angle at Center in Degrees	Number of Sides	Angle at Center in Degrees
3	120	9	40	15	24
4	90	10	36	16	$22\,1/2$
5	72	11	$32\,8/11$	17	$21\,3/17$
6	60	12	30	18	20
7	$51\,3/7$	13	$27\,9/13$	19	$18\,18/19$
8	45	14	$25\,5/7$	20	18

Ellipse

An Ellipse is a curve for which the sum of the distances of any point on it from two fixed points (the *foci*) is constant.

48. To describe an ellipse for which the axes are given (Fig. 61). Let *AB* be the *major* and *RS* the *minor* axis ($AB > RS$). With *O* as center, and *OB* and *OR* as radii, describe circles. From *O* draw any radial line intersecting the circles at *M* and *N*. Through *M* draw a line parallel to *OR*, and through *N* a line parallel to *OB*. These lines intersect at *H*, a point on the ellipse. Repeat the construction to obtain other points.

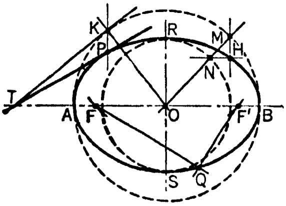

Fig. 61

49. To locate the foci of an ellipse, having given the axes (Fig. 61). With *R* as center, and radius equal to *AO*, describe arcs intersecting *AB* at *F* and *F'*, the required foci.

50. To describe an ellipse mechanically, having given an axis and the foci (Fig. 61). A cord of length equal to the major axis is pinned or fixed at its ends to the foci *F* and *F′*. With a pencil inside the loop, keeping the cord taut so as to guide the pencil point, trace the outline of the ellipse (*Q* represents the pencil point and length *FQF′* the cord). If the minor axis *RS* is given rather than the major axis *AB*, the length *AB* (for the cord) is readily determined as *FR* + *RF′*.

51. To draw a tangent to a given ellipse through a given point.

Case 1. Point *P* is on the curve (Fig. 61). With *O* as center, and *OB* as radius, describe a circle. Through *P* draw a line parallel to *OR*, intersecting the circle at *K*. Through *K* draw a tangent to the circle, intersecting the major axis at *T*. *PT* is the required tangent.

Case 2. Point *P* is not on the curve (Fig. 62). With *P* as center, and radius *PF′*, describe an arc. With *F* as center, and radius *AB*, describe an arc intersecting the first arc at *M* and *N*. Draw *FM* and *FN*, intersecting the ellipse at *E* and *G*. *PE* and *PG* are the required tangents.

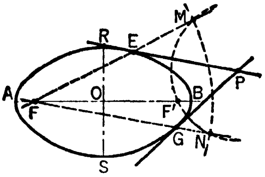

FIG. 62

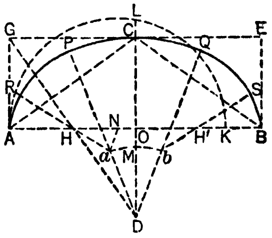

FIG. 63

52. To describe an ellipse approximately by means of circular arcs of three radii (Fig. 63). On the major axis *AB* draw the rectangle *BG* of altitude equal to half the minor axis, *OC*; to the diagonal *AC* draw the perpendicular *GHD*; set off *OK* equal to *OC*, and describe a semicircle on *AK*; produce *OC* to *L*; set off *OM* equal to *CL*, and from *D* describe an arc with radius *DM*; from *A*, with radius *OL*, draw an arc cutting *AB* at *N*; from *H*, with radius *HN*, draw an arc cutting arc *ab* at *a*. Thus the five centers *H*, *a*, *D*, *b*, *H′*, are found, from which the arcs *AR*, *RP*, *PQ*, *QS*, *SB*, are described. The part of the ellipse below axis *AB* can be constructed in like manner.

Parabola

A Parabola is a curve for which the distance of any point on it from a fixed line (the *directrix*) is equal to its distance from a fixed point (the *focus*). For a general discussion of its properties, see the section on analytic geometry.

53. To describe a parabola for which the vertex, the axis, and a point of the curve are given (Fig. 64). Let *A* be the given vertex, *AB* the given axis, and *M* the given point. Construct the rectangle *ABMC*. Divide *MC* and *CA* into the same number of equal parts (say four), numbering the divisions consecutively in the manner shown. Connect *A*1, *A*2, and *A*3. Through 1′, 2′, 3′, draw parallels to the axis *AB*. The intersections *I*, *II*, and *III*, of these lines are points on the required curve. A similar construction below the axis will give the other symmetrical branch of the curve.

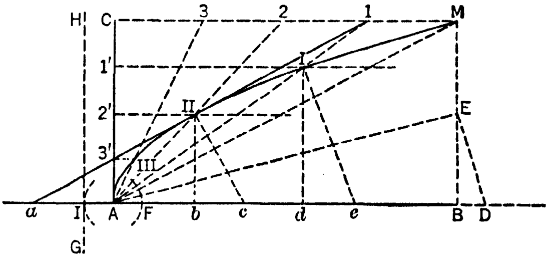

FIG. 64

54. To locate the focus and directrix of a parabola, having given the vertex, the axis, and a point of the curve (Fig. 64). Let *A* be the given vertex, *AB* the given axis, and *M* the given point. Drop the perpendicular *MB* from *M* to *AB*. Bisect it at *E* and draw *AE*. Draw *ED* perpendicular to *AE* at *E* and intersecting the axis at *D*. With *A* as center and bD as radius, describe arcs cutting the axis at F and I. Then F is the focus, and the line GH, perpendicular to the axis through I, is the directrix.

55. To describe a parabola mechanically, having given the focus and directrix (Fig. 65). Let F be the given focus and EN the given directrix. Place a straight-edge to the directrix EN, and apply to it a square, LEG. Fasten to the end G one end of a cord equal in length to the edge EG, and attach the other end to the focus F; slide the square along the straight-edge, holding the cord taut against the edge of the square by a pencil D, by which the parabolic curve is described.

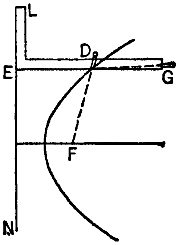

Fig. 65

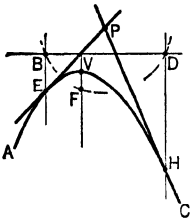

Fig. 66

56. To draw a tangent to a given parabola through a given point.

Case 1. The point is on the curve (Fig. 64). Let H be the given point. Drop a perpendicular from H to the axis, cutting it at b. Make Aa equal to Ab. Then a line through a and H is the required tangent. The line Hc perpendicular to the tangent at H is the *normal* at that point; bc is the *subnormal*. All subnormals of a given parabola are equal to the distance from the directrix to the focus and hence equal to each other. Thus the subnormal at I is de equal to bc, where d is the foot of the perpendicular dropped from I. The tangent at I can be drawn as a perpendicular to Ie through I.

Case 2. The point is off the curve (on the convex side) (Fig. 66). Let P be the given point and F the focus of the parabola. With P as center, and PF as radius, draw arcs intersecting the directrix at B and D. Through B and D draw lines parallel to the axis, intersecting the parabola at E and H. PE and PH are the required tangents.

Hyperbola

An Hyperbola is a curve for which the difference of the distances of any point on it from two fixed points (the *foci*) is constant. It has two distinct branches.

57. To describe an hyperbola for which the foci and the difference of the focal radii are given (Fig. 67). Let F and F' be the given foci and AOB the given difference of the focal radii. Lay out AOB (the transverse axis) so that $AF = F'B$ and $AO = OB$. A and B are points on the required curve. With centers F and F', and any radius greater than FB or $F'A$, describe arcs aa. With the same centers, and radius equal to the difference between the first radius and the transverse axis AOB, describe arcs bb, intersecting arcs aa at P, Q, R, and S, points on the required curve. Repeat the construction for additional points.

Make $BC = BC' = OF = OF'$, and construct the rectangle $DEFG$. The diagonals DF and EG, produced, are called *asymptotes*. The hyperbola is tangent to its asymptotes at infinity.

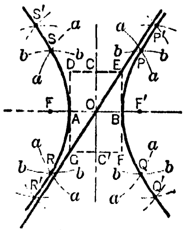

Fig. 67

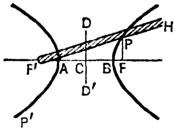

Fig. 68

58. To locate the foci of an hyperbola, having given the axes (Fig. 67). With O as center and radius equal to BC, describe arcs intersecting AB extended, at F and F', the required foci.

59. To describe an hyperbola mechanically, having given the foci and the difference of the focal radii (Fig. 68). Let F and F' be the given foci and AB the given difference of focal radii. Using a ruler longer than the distance $F'F$, fasten one of its extremities at the focus F'. At the other extremity H attach a cord of such a length that the length of the ruler shall exceed the length of the cord by the given distance AB. Attach the other extremity of the cord at the focus F. Press a pencil P against the ruler, and keep the cord constantly taut while the ruler is turned around F' as a center. The point of the pencil will describe one branch of the curve, and the other can be obtained in like manner

60. To draw a tangent to a given hyperbola through a given point.

Case 1. Point P is on the curve (Fig. 69). Draw lines connecting P with the foci. Bisect the angle $F'PF$. The bisecting line TP is the required tangent.

Case 2. Point P is off the curve on the convex side (Fig. 70). With P as center and radius PF', describe an arc. With F as center, and radius AB, describe an arc intersecting the first arc at M and N. Produce lines FM and FN to intersect the curve at E and G. PE and PG are the required tangents.

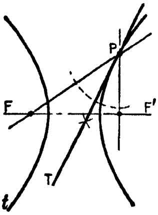

Fig. 69

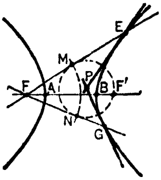

Fig. 70

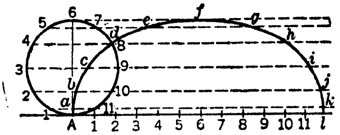

Fig. 71

Cycloid

A Cycloid is a curve generated by a point on a circle rolling on a straight line.

61. To describe a cycloid for which the generating circle is given (Fig. 71). Let A be the generating point. Divide the circumference of the generating circle into an even number of equal arcs, as $A1$, 1-2, etc., and set off the rectified arcs on the base. Through the points 1, 2, 3, etc., on the circle, draw horizontal lines, and on them set off distances $1a = A1$, $2b = A2$, $3c = A3$, etc. The points A, a, b, c, etc., are points of the cycloid.

An Epicycloid is a curve generated by a point on one circle rolling on the *outside* of another circle. **An Hypocycloid** is a curve generated by the point if the generating circle rolls on the *inside* of the second circle.

Involute of a Circle

An Involute of a Circle is a curve generated by the free end of a taut string as it is unwound from a circle.

62. To describe an involute of a given circle (Fig. 72). Let AB be the given circle. Through B draw Bb perpendicular to AB. Make Bb equal in length to half the circumference of the circle. Divide Bb and the semi-circumference into the same number of equal parts, say six. From each point of division 1, 2, 3, etc., of the circumference, draw lines to the center C of the circle. Then draw $1a_1$ perpendicular to $C1$; $2a_2$ perpendicular to $C2$; and so on. Make $1a_1$ equal to bb_1; $2a_2$ equal to bb_2; $3a_3$ equal to bb_3; and so on. Join the points A, a_1, a_2, a_3, etc., by a curve; this curve is the required involute.

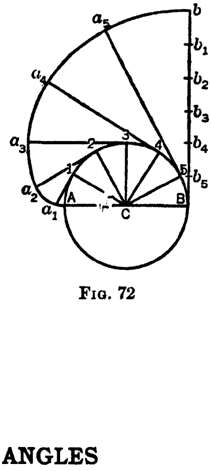

Fig. 72

TRIGONOMETRY

By M. J. Fish

24. CIRCULAR FUNCTIONS OF PLANE ANGLES

Definitions and Values

Trigonometric Functions. The angle α in Fig. 1, is measured in degrees or radians, as defined in Art. 21. The ratio of any two of the quantities x, y, or r determines the extent of the opening between the lines OP and OX. Since these ratios are functions of the angle they may be used to measure or construct it. The definitions and terms used to designate the functions are as follows:

$$\text{Sine } \alpha = \frac{y}{r} = \sin \alpha$$

$$\text{Cosine } \alpha = \frac{x}{r} = \cos \alpha$$

$$\text{Tangent } \alpha = \frac{y}{x} = \tan \alpha$$

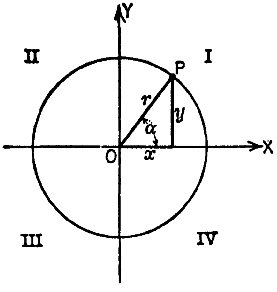

FIG. 1

$$\text{Cotangent } \alpha = \frac{x}{y} = \cot \alpha$$

$$\text{Secant } \alpha = \frac{r}{x} = \sec \alpha$$

$$\text{Cosecant } \alpha = \frac{r}{y} = \csc \alpha$$

$$\text{Versine } \alpha = \frac{r - x}{r} = \text{vers } \alpha = 1 - \cos \alpha$$

$$\text{Coversine } \alpha = \frac{r - y}{r} = \text{covers } \alpha = 1 - \sin \alpha$$

$$\text{Haversine } \alpha = \frac{r - x}{2r} = \text{hav } \alpha = \frac{1}{2} \text{ vers } \alpha$$

Positive and Negative Values. An angle α (Fig. 1), if measured in a *counter-clockwise* direction, is said to be *positive*; if measured *clockwise*, *negative*. Following the convention that x is positive if measured along OX to the right of the OY axis and negative if measured to the left, and similarly, y is positive if measured along OY above the OX axis and negative if measured below, the signs of the trigonometric functions are different for angles in the quadrants I, II, III, and IV. The signs of the six most common functions are tabulated in Table I.

Table I. Signs of Trigonometric Functions

Quadrant	sin	cos	tan	cot	sec	csc
I	+	+	+	+	+	+
II	+	−	−	−	−	+
III	−	−	+	+	−	−
IV	−	+	−	−	+	−

Values of Trigonometric Functions are periodic, the period of the sin, cos, sec, csc being 2π radians, and that of the tan and cot, π radians. For example, in Fig. 2, (n an integer)

$$\sin (\alpha + 2\pi n) = \sin \alpha$$
$$\tan (\alpha + \pi n) = \tan \alpha$$

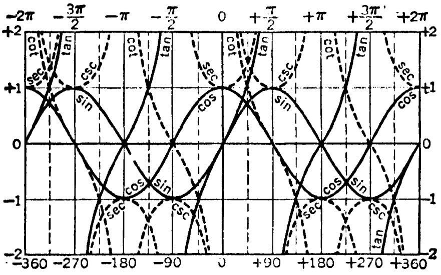

FIG. 2

Functions of angles in any quadrant (Fig. 1) in terms of angles in the first quadrant, and values of the functions for certain angles are given in Tables II and III, respectively. Values of the functions for angles in increments of one minute and five hundredths of a degree may be obtained from Section 1, Table 17. Combined with this table is a table of common logarithms of the functions.

Table II. Functions of Angles in Any Quadrant in Terms of Angles in the First Quadrant

	$-\alpha$	$90° \pm \alpha$	$180° \pm \alpha$	$270° \pm \alpha$	$360° \pm \alpha$
sin	$-\sin \alpha$	$+\cos \alpha$	$\mp \sin \alpha$	$-\cos \alpha$	$\pm \sin \alpha$
cos	$+\cos \alpha$	$\mp \sin \alpha$	$-\cos \alpha$	$\pm \sin \alpha$	$+\cos \alpha$
tan	$-\tan \alpha$	$\mp \cot \alpha$	$\pm \tan \alpha$	$\mp \cot \alpha$	$\pm \tan \alpha$
cot	$-\cot \alpha$	$\mp \tan \alpha$	$\pm \cot \alpha$	$\mp \tan \alpha$	$\pm \cot \alpha$
sec	$+\sec \alpha$	$\mp \csc \alpha$	$-\sec \alpha$	$\pm \csc \alpha$	$+\sec \alpha$
csc	$-\csc \alpha$	$+\sec \alpha$	$\mp \csc \alpha$	$-\sec \alpha$	$\pm \csc \alpha$

Table III. Functions of Certain Angles

	0°	30°	45°	60°	90°	180°	270°	360°
sin	0	$1/2$	$1/2\sqrt{2}$	$1/2\sqrt{3}$	1	0	−1	0
cos	1	$1/2\sqrt{3}$	$1/2\sqrt{2}$	$1/2$	0	−1	0	1
tan	0	$1/3\sqrt{3}$	1	$\sqrt{3}$	∞	0	∞	0
cot	∞	$\sqrt{3}$	1	$1/3\sqrt{3}$	0	∞	0	∞
sec	1	$2/3\sqrt{3}$	$\sqrt{2}$	2	∞	−1	∞	1
csc	∞	2	$\sqrt{2}$	$2/3\sqrt{3}$	1	∞	−1	∞

Inverse, or Anti-functions. The symbol $\sin^{-1} x$ means the angle whose sine is x, and is read inverse sine of x, anti-sine of x, or arc sine x. Similarly for $\cos^{-1} x$, $\tan^{-1} x$, $\cot^{-1} x$, $\sec^{-1} x$, $\csc^{-1} x$, $\text{vers}^{-1} x$, the last meaning an angle α such that $(1 - \cos\alpha) = x$. While the direct functions (sine, etc.) are single valued the indirect are many valued; thus $\sin 30° = 0.5$, but $\sin^{-1} 0.5 = 30°, 150°, ..$

Functional Relationships, Identities

Table IV. Functions of an Angle in Terms of Each of the Others

	$\sin\alpha = a$	$\cos\alpha = a$	$\tan\alpha = a$	$\cot\alpha = a$	$\sec\alpha = a$	$\csc\alpha = a$
sin	a	$\sqrt{1-a^2}$	$\dfrac{a}{\sqrt{1+a^2}}$	$\dfrac{1}{\sqrt{1+a^2}}$	$\dfrac{\sqrt{a^2-1}}{a}$	$\dfrac{1}{a}$
cos	$\sqrt{1-a^2}$	a	$\dfrac{1}{\sqrt{1+a^2}}$	$\dfrac{a}{\sqrt{1+a^2}}$	$\dfrac{1}{a}$	$\dfrac{\sqrt{a^2-1}}{a}$
tan	$\dfrac{a}{\sqrt{1-a^2}}$	$\dfrac{\sqrt{1-a^2}}{a}$	a	$\dfrac{1}{a}$	$\sqrt{a^2-1}$	$\dfrac{1}{\sqrt{a^2-1}}$
cot	$\dfrac{\sqrt{1-a^2}}{a}$	$\dfrac{a}{\sqrt{1-a^2}}$	$\dfrac{1}{a}$	a	$\dfrac{1}{\sqrt{a^2-1}}$	$\sqrt{a^2-1}$
sec	$\dfrac{1}{\sqrt{1-a^2}}$	$\dfrac{1}{a}$	$\sqrt{1+a^2}$	$\dfrac{\sqrt{1+a^2}}{a}$	a	$\dfrac{a}{\sqrt{a^2-1}}$
csc	$\dfrac{1}{a}$	$\dfrac{1}{\sqrt{1-a^2}}$	$\dfrac{\sqrt{1+a^2}}{a}$	$\sqrt{1+a^2}$	$\dfrac{a}{\sqrt{a^2-1}}$	a

Note: The sign of the radical is to be determined by the quadrant.

Functions of the Sum and Difference of Two Angles.

$$\sin(\alpha \pm \beta) = \sin\alpha\cos\beta \pm \cos\alpha\sin\beta$$
$$\cos(\alpha \pm \beta) = \cos\alpha\cos\beta \mp \sin\alpha\sin\beta$$
$$\tan(\alpha \pm \beta) = (\tan\alpha \pm \tan\beta)/(1 \mp \tan\alpha\tan\beta)$$
$$\cot(\alpha \pm \beta) = (\cot\beta\cot\alpha \mp 1)/(\cot\beta \pm \cot\alpha).$$

If x is small, say 3° or 4°, then the following are close approximations, in which the quantity x is to be expressed in radians (1° = 0.01745 radian).

$$\sin\alpha \approx \alpha, \qquad \cos\alpha \approx 1, \qquad \tan\alpha \approx \alpha$$
$$\sin(\alpha \pm x) \approx \sin\alpha \pm x\cos\alpha, \qquad \cos(\alpha \pm x) \approx \cos\alpha \mp x\sin\alpha$$

Functions of Half Angles.

$$\sin {}^1\!/_2\,\alpha = \sqrt{{}^1\!/_2(1 - \cos\alpha)} = {}^1\!/_2\sqrt{1 + \sin\alpha} - {}^1\!/_2\sqrt{1 - \sin\alpha}$$
$$\cos {}^1\!/_2\,\alpha = \sqrt{{}^1\!/_2(1 + \cos\alpha)} = {}^1\!/_2\sqrt{1 + \sin\alpha} + {}^1\!/_2\sqrt{1 - \sin\alpha}$$
$$\tan {}^1\!/_2\,\alpha = \sqrt{(1 - \cos\alpha)/(1 + \cos\alpha)} = (1 - \cos\alpha)/\sin\alpha = \sin\alpha/(1 + \cos\alpha)$$
$$\cot {}^1\!/_2\,\alpha = \sqrt{(1 + \cos\alpha)/(1 - \cos\alpha)} = (1 + \cos\alpha)/\sin\alpha = \sin\alpha/(1 - \cos\alpha)$$

Functions of Multiples of Angles.

$$\sin 2\alpha = 2\sin\alpha\cos\alpha, \qquad \cos 2\alpha = 2\cos^2\alpha - 1 = 1 - 2\sin^2\alpha$$
$$\tan 2\alpha = 2\tan\alpha/(1 - \tan^2\alpha) \qquad \cot 2\alpha = (\cot^2\alpha - 1)/2\cot\alpha$$

$\sin 3\alpha = 3 \sin \alpha - 4 \sin^3 \alpha \qquad \cos 3\alpha = 4 \cos^3 \alpha - 3 \cos \alpha$

$\sin 4\alpha = 8 \cos^3 \alpha \sin \alpha - 4 \cos \alpha \sin \alpha \qquad \cos 4\alpha = 8 \cos^4 \alpha - 8 \cos^2 \alpha + 1$

Products and Powers of Functions.

$$\sin \alpha \sin \beta = {}^1/_2 \cos (\alpha - \beta) - {}^1/_2 \cos (\alpha + \beta)$$

$$\cos \alpha \cos \beta = {}^1/_2 \cos (\alpha - \beta) + {}^1/_2 \cos (\alpha + \beta)$$

$$\sin \alpha \cos \beta = {}^1/_2 \sin (\alpha - \beta) + {}^1/_2 \sin (\alpha + \beta)$$

$$\tan \alpha \cot \alpha = \sin \alpha \csc \alpha = \cos \alpha \sec \alpha = 1$$

$$\sin^2 \alpha = {}^1/_2 (1 - \cos 2\alpha); \qquad \cos^2 \alpha = {}^1/_2 (1 + \cos 2\alpha)$$

$$\sin^3 \alpha = {}^1/_4 (3 \sin \alpha - \sin 3\alpha); \qquad \cos^3 \alpha = {}^1/_4 (\cos 3\alpha + 3 \cos \alpha)$$

Sums and Differences of Functions.

$$\sin \alpha + \sin \beta = 2 \sin {}^1/_2 (\alpha + \beta) \cos {}^1/_2 (\alpha - \beta)$$

$$\sin \alpha - \sin \beta = 2 \cos {}^1/_2 (\alpha + \beta) \sin {}^1/_2 (\alpha - \beta)$$

$$\cos \alpha + \cos \beta = 2 \cos {}^1/_2 (\alpha + \beta) \cos {}^1/_2 (\alpha - \beta)$$

$$\cos \alpha - \cos \beta = - 2 \sin {}^1/_2 (\alpha + \beta) \sin {}^1/_2 (\alpha - \beta)$$

$$\tan \alpha + \tan \beta = \frac{\sin (\alpha + \beta)}{\cos \alpha \cos \beta}; \qquad \cot \alpha + \cot \beta = \frac{\sin (\alpha + \beta)}{\sin \alpha \sin \beta}$$

$$\tan \alpha - \tan \beta = \frac{\sin (\alpha - \beta)}{\cos \alpha \cos \beta}; \qquad \cot \alpha - \cot \beta = -\frac{\sin (\alpha - \beta)}{\sin \alpha \sin \beta}$$

$$\sin^2 \alpha - \sin^2 \beta = \sin (\alpha + \beta) \sin (\alpha - \beta)$$

$$\cos^2 \alpha - \cos^2 \beta = - \sin (\alpha + \beta) \sin (\alpha - \beta)$$

$$\cos^2 \alpha - \sin^2 \beta = \cos (\alpha + \beta) \cos (\alpha - \beta)$$

Anti-Trigonometric or Inverse Functional Relations. In the following formulas the periodic constant is omitted.

$$\sin^{-1} x = - \sin^{-1}(- x) = \frac{\pi}{2} - \cos^{-1} x = \cos^{-1}\sqrt{1 - x^2} = \tan^{-1} \frac{x}{\sqrt{1 - x^2}} = \cot^{-1} \frac{\sqrt{1 - x^2}}{x}$$

$$= \csc^{-1} \frac{1}{x} = \sec^{-1} \frac{1}{\sqrt{1 - x^2}}$$

$$\cos^{-1} x = \pi - \cos^{-1} (- x) = \frac{\pi}{2} - \sin^{-1} x = {}^1/_2 \cos^{-1} (2 x^2 - 1) = \sin^{-1} \sqrt{1 - x^2}$$

$$= \tan^{-1} \frac{\sqrt{1 - x^2}}{x} = \cot^{-1} \frac{x}{\sqrt{1 - x^2}} = \sec^{-1} \frac{1}{x} = \csc^{-1} \frac{1}{\sqrt{1 - x^2}}$$

$$\tan^{-1} x = - \tan^{-1} (- x) = \frac{\pi}{2} - \cot^{-1} x = \sin^{-1} \frac{x}{\sqrt{1 + x^2}} = \cos^{-1} \frac{1}{\sqrt{1 + x^2}} = \cot^{-1} \frac{1}{x}$$

$$= \sec^{-1} \sqrt{1 + x^2} = \csc^{-1} \frac{\sqrt{1 + x^2}}{x}$$

$$\cot^{-1} x = \tan^{-1} \frac{1}{x}; \quad \sec^{-1} x = \cos^{-1} \frac{1}{x}; \quad \csc^{-1} x = \sin^{-1} \frac{1}{x}$$

$$\sin^{-1} x \pm \sin^{-1} y = \sin^{-1}\{x \sqrt{1 - y^2} \pm y \sqrt{1 - x^2}\}$$

$$\cos^{-1} x \pm \cos^{-1} y = \cos^{-1}\{xy \mp \sqrt{(1 - x^2)(1 - y^2)}\}$$

$$\sin^{-1} x \pm \cos^{-1} y = \sin^{-1}\{xy \pm \sqrt{(1 - x^2)(1 - y^2)}\} = \cos^{-1}\{y \sqrt{1 - x^2} \mp x \sqrt{1 - y^2}\}$$

$$\tan^{-1} x \pm \tan^{-1} y = \tan^{-1} \frac{x \pm y}{1 \mp xy}$$

$$\tan^{-1} x \pm \cot^{-1} y = \tan^{-1} \frac{xy \pm 1}{y \mp x} = \cot^{-1} \frac{y \mp x}{xy \pm 1}$$

25. SOLUTION OF TRIANGLES

Relations Between Angles and Sides of Plane Triangles. Let a, b, c = sides of triangle; α, β, γ = angles opposite a, b, c, respectively; A = area of triangle; $s = {}^1/_2 (a + b + c)$.

$$\frac{a}{\sin \alpha} = \frac{b}{\sin \beta} = \frac{c}{\sin \gamma} \qquad \text{(Law of Sines)}$$

$$a^2 = b^2 + c^2 - 2bc\cos\alpha \quad \text{(Law of Cosines)}$$

$$\frac{a-b}{a+b} = \frac{\tan {}^1/_2\,(\alpha-\beta)}{\tan {}^1/_2\,(\alpha+\beta)} \quad \text{(Law of Tangents)}$$

$$\alpha + \beta + \gamma = 180^\circ$$

$$a = b\cos\gamma + c\cos\beta;\ b = c\cos\alpha + a\cos\gamma;\ c = a\cos\beta + b\cos\alpha$$

$$A = \sqrt{s(s-a)(s-b)(s-c)}$$

$$\sin\alpha = \frac{2}{bc}A;\ \sin\beta = \frac{2}{ca}A;\ \sin\gamma = \frac{2}{ab}A$$

$$\sin\frac{\alpha}{2} = \sqrt{\frac{(s-b)(s-c)}{bc}};\ \sin\frac{\beta}{2} = \sqrt{\frac{(s-c)(s-a)}{ca}};\ \sin\frac{\gamma}{2} = \sqrt{\frac{(s-a)(s-b)}{ab}}$$

$$\cos\frac{\alpha}{2} = \sqrt{\frac{s(s-a)}{bc}};\ \cos\frac{\beta}{2} = \sqrt{\frac{s(s-b)}{ca}};\ \cos\frac{\gamma}{2} = \sqrt{\frac{s(s-c)}{ab}}$$

$$\tan\frac{\alpha}{2} = \sqrt{\frac{(s-b)(s-c)}{s(s-a)}};\ \tan\frac{\beta}{2} = \sqrt{\frac{(s-c)(s-a)}{s(s-b)}};\ \tan\frac{\gamma}{2} = \sqrt{\frac{(s-a)(s-b)}{s(s-c)}}$$

Solution of Plane Oblique Triangles.

Given a, b, c. (If logarithms are to be used, use 1.)

1. $r = \sqrt{\dfrac{(s-a)(s-b)(s-c)}{s}};\ A = \sqrt{s(s-a)(s-b)(s-c)} = rs;$

$$\tan\frac{\alpha}{2} = \frac{r}{s-a};\ \tan\frac{\beta}{2} = \frac{r}{s-b};\ \tan\frac{\gamma}{2} = \frac{r}{s-c}.$$

2. $\cos\alpha = \dfrac{b^2+c^2-a^2}{2bc};\ \cos\beta = \dfrac{a^2+c^2-b^2}{2ac};$

$$\cos\gamma = \frac{a^2+b^2-c^2}{2ab},\ \text{or}\ \gamma = 180^\circ - (\alpha+\beta).$$

Given a, b, α.

$\sin\beta = \dfrac{b\sin\alpha}{a}$ (if $a > b$, $\beta < \frac{\pi}{2}$ and has only one value; if $b > a$, β has two values, β_1 and $\beta_2 = 180^\circ - \beta_1$); $\gamma = 180^\circ - (\alpha+\beta)$; $c = \dfrac{a\sin\gamma}{\sin\alpha}$; $A = {}^1/_2\,ab\sin\gamma$.

Given a, α, β.

$$b = \frac{a\sin\beta}{\sin\alpha};\ \gamma = 180^\circ - (\alpha+\beta);\ c = \frac{a\sin\gamma}{\sin\alpha};\ A = {}^1/_2\,ab\sin\gamma.$$

Given a, b, γ. (If logarithms are to be used, use 1.)

1. $\tan {}^1/_2\,(\alpha-\beta) = \dfrac{a-b}{a+b}\cot {}^1/_2\,\gamma;\ {}^1/_2\,(\alpha+\beta) = 90^\circ - {}^1/_2\,\gamma;\ c = \dfrac{a\sin\gamma}{\sin\alpha}$

   $A = {}^1/_2\,ab\sin\gamma$.

2. $c = \sqrt{a^2+b^2-2\,ab\cos\gamma};\ \sin\alpha = \dfrac{a\sin\gamma}{c};\ \beta = 180^\circ - (\alpha+\gamma)$.

3. $\tan\alpha = \dfrac{a\sin\gamma}{b-a\cos\gamma};\ \beta = 180^\circ - (\alpha+\gamma);\ c = \dfrac{a\sin\gamma}{\sin\alpha}$.

Solution of Plane Right Triangles. Let $\gamma = 90^\circ$ and c be the hypotenuse. Given any two sides or one side and an acute angle α.

$$a = \sqrt{c^2-b^2} = \sqrt{(c+b)(c-b)} = b\tan\alpha = c\sin\alpha.$$

$$b = \sqrt{c^2-a^2} = \sqrt{(c+a)(c-a)} = \frac{a}{\tan\alpha} = c\cos\alpha.$$

$$c = \sqrt{a^2+b^2} = \frac{a}{\sin\alpha} = \frac{b}{\cos\alpha}.$$

$$\alpha = \sin^{-1}\frac{a}{c} = \cos^{-1}\frac{b}{c} = \tan^{-1}\frac{a}{b};\ \beta = 90^\circ - \alpha.$$

$$A = \frac{ab}{2} = \frac{a^2}{2\tan\alpha} = \frac{b^2\tan\alpha}{2} = \frac{c^2\sin 2\alpha}{4}.$$

26. SPHERICAL TRIGONOMETRY

Spherical Trigonometry. Let O be the center of the sphere and a, b, c the sides of a triangle on the surface with opposite angles α, β, γ, respectively, the sides being measured by the angle subtended at the center of the sphere. Let $s = {}^1/_2\,(a + b + c)$, $\sigma = {}^1/_2\,(\alpha + \beta + \gamma)$, $E = \alpha + \beta + \gamma - 180°$, the spherical excess. The following formulas are valid usually only for triangles of which the sides and angles are all between 0° and 180°. To each such triangle there is a polar triangle, whose sides are $180° - \alpha$, $180° - \beta$, $180° - \gamma$, and whose angles are $180° - a$, $180° - b$, $180° - c$.

General Formulas.

$$\frac{\sin a}{\sin \alpha} = \frac{\sin b}{\sin \beta} = \frac{\sin c}{\sin \gamma} \quad \text{(Law of Sines)}$$

$$\cos a = \cos b \cos c + \sin b \sin c \cos \alpha \quad \text{(Law of Cosines)}$$

$$\cos \alpha = -\cos \beta \cos \gamma + \sin \beta \sin \gamma \cos a \quad \text{(Law of Cosines)}$$

$$\cos a \sin b = \sin a \cos b \cos \gamma + \sin c \cos \alpha$$

$$\cot a \sin b = \sin \gamma \cot \alpha + \cos \gamma \cos b$$

$$\cos \alpha \sin \beta = \sin \gamma \cos a - \sin \alpha \cos \beta \cos c$$

$$\cot \alpha \sin \beta = \sin c \cot a - \cos c \cos \beta$$

$$\sin \frac{a}{2} = \sqrt{\frac{-\cos \sigma \cos (\sigma - \alpha)}{\sin \beta \sin \gamma}}\,; \quad \sin \frac{\alpha}{2} = \sqrt{\frac{\sin (s - b) \sin (s - c)}{\sin b \sin c}}\,:$$

$$\cos \frac{a}{2} = \sqrt{\frac{\cos (\sigma - \beta) \cos (\sigma - \gamma)}{\sin \beta \sin \gamma}}\,; \quad \cos \frac{\alpha}{2} = \sqrt{\frac{\sin s \sin (s - a)}{\sin b \sin c}}$$

$$\tan \frac{a}{2} = \sqrt{\frac{-\cos \sigma \cos (\sigma - \alpha)}{\cos (\sigma - \beta) \cos (\sigma - \gamma)}}\,; \quad \tan \frac{\alpha}{2} = \sqrt{\frac{\sin (s - b) \sin (s - c)}{\sin s \sin (s - a)}}$$

$$\tan \frac{E}{4} = \sqrt{\tan \frac{s}{2} \tan \frac{(s - a)}{2} \tan \frac{(s - b)}{2} \tan \frac{(s - c)}{2}}\,; \quad \cot \frac{E}{2} = \frac{\cot \frac{a}{2} \cot \frac{b}{2} + \cos \gamma}{\sin \gamma}$$

$$\tan \left(\frac{a + b}{2}\right) = \frac{\cos \left(\frac{\alpha - \beta}{2}\right)}{\cos \left(\frac{\alpha + \beta}{2}\right)} \tan \frac{c}{2}\,; \quad \tan \left(\frac{a - b}{2}\right) = \frac{\sin \left(\frac{\alpha - \beta}{2}\right)}{\sin \left(\frac{\alpha + \beta}{2}\right)} \tan \frac{c}{2}$$

$$\tan \left(\frac{\alpha + \beta}{2}\right) = \frac{\cos \left(\frac{a - b}{2}\right)}{\cos \left(\frac{a + b}{2}\right)} \cot \frac{\gamma}{2}\,; \quad \tan \left(\frac{\alpha - \beta}{2}\right) = \frac{\sin \left(\frac{a - b}{2}\right)}{\sin \left(\frac{a + b}{2}\right)} \cot \frac{\gamma}{2}$$

$$\cos \left(\frac{\alpha + \beta}{2}\right) \cos \frac{c}{2} = \cos \left(\frac{a + b}{2}\right) \sin \frac{\gamma}{2}\,; \quad \sin \left(\frac{\alpha + \beta}{2}\right) \cos \frac{c}{2} = \cos \left(\frac{a - b}{2}\right) \cos \frac{\gamma}{2}$$

$$\cos \left(\frac{\alpha - \beta}{2}\right) \sin \frac{c}{2} = \sin \left(\frac{a + b}{2}\right) \sin \frac{\gamma}{2}\,; \quad \sin \left(\frac{\alpha - \beta}{2}\right) \sin \frac{c}{2} = \sin \left(\frac{a - b}{2}\right) \cos \frac{\gamma}{2}$$

The Right Spherical Triangle Let $\gamma = 90°$ and c be the hypotenuse.

$$\cos c = \cos a \cos b = \cot \alpha \cot \beta;\ \cos a = \frac{\cos \alpha}{\sin \beta};\ \cos b = \frac{\cos \beta}{\sin \alpha};\ \sin \alpha = \frac{\sin a}{\sin c};\ \cos \alpha = \frac{\tan b}{\tan c};$$

$$\tan \alpha = \frac{\tan a}{\sin b}$$

27. HYPERBOLIC TRIGONOMETRY

Hyperbolic Angles are defined in a manner similar to circular angles but with reference to an *equilateral hyperbola*. The comparative relations are shown in Figs. 3 and 4. A *circular angle* is a central angle measured in radians by the ratio s/r or the ratio $2A/r^2$, where A is the area of the sector included by the angle α and the arc s (Fig. 3). For the *hyperbola* the radius ρ is not constant and only the value of the *differential hyperbolic angle* $d\theta$ is defined by the ratio ds/ρ. Thus, $\theta = \int ds/\rho = 2A/a^2$, where A repre-

sents the shaded area in Fig. 4. If both s and ρ are measured in the same units the angle is expressed in *hyperbolic radians.*

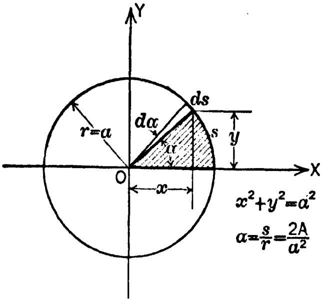

FIG. 3

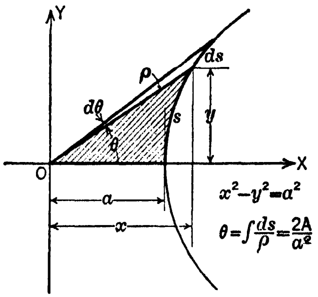

FIG. 4

Hyperbolic Functions are defined by ratios similar to those defining functions of circular angles and also named similarly. Their names and abbreviations are:

Hyperbolic sine $\theta = \frac{y}{a} = \sinh\theta$

Hyperbolic cosine $\theta = \frac{x}{a} = \cosh\theta$

Hyperbolic tangent $\theta = \frac{y}{x} = \tanh\theta$

Hyperbolic cotangent $\theta = \frac{x}{y} = \coth\theta$

Hyperbolic secant $\theta = \frac{a}{x} = \operatorname{sech}\theta$

Hyperbolic cosecant $\theta = \frac{a}{y} = \operatorname{csch}\theta$

Values and Exponential Equivalents. The values of hyperbolic functions may be computed from their exponential equivalents. The graphs are shown in Fig. 5. Values for increments of 0.01 radian are given in Section 1, Table 18.

$$\sinh\theta = \frac{e^{\theta}-e^{-\theta}}{2}; \quad \cosh\theta = \frac{e^{\theta}+e^{-\theta}}{2}; \quad \tanh\theta = \frac{e^{\theta}-e^{-\theta}}{e^{\theta}+e^{-\theta}}$$

If θ is extremely small, $\sinh\theta \approx \theta$, $\cosh\theta \approx 1$, and $\tanh\theta \approx \theta$. For large values of θ, $\sinh\theta \approx \cosh\theta$, and $\tanh\theta \approx \coth\theta \approx 1$.

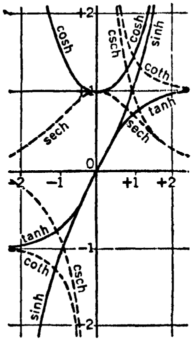

FIG. 5

Fundamental Identities.

$$\operatorname{csch}\theta = \frac{1}{\sinh\theta}; \quad \operatorname{sech}\theta = \frac{1}{\cosh\theta}; \quad \coth\theta = \frac{1}{\tanh\theta}$$

$$\cosh^2\theta - \sinh^2\theta = 1; \quad \operatorname{sech}^2\theta = 1 - \tanh^2\theta;$$
$$\operatorname{csch}^2\theta = \coth^2\theta - 1$$

$$\cosh\theta + \sinh\theta = e^{\theta}; \quad \cosh\theta - \sinh\theta = e^{-\theta}$$

$$\sinh(-\theta) = -\sinh\theta; \quad \cosh(-\theta) = \cosh\theta$$

$$\tanh(-\theta) = -\tanh\theta; \quad \coth(-\theta) = -\coth\theta$$

$$\sinh(\theta_1 \pm \theta_2) = \sinh\theta_1\cosh\theta_2 \pm \cosh\theta_1\sinh\theta_2$$

$$\cosh(\theta_1 \pm \theta_2) = \cosh\theta_1\cosh\theta_2 \pm \sinh\theta_1\sinh\theta_2$$

$$\tanh(\theta_1 \pm \theta_2) = \frac{\tanh\theta_1 \pm \tanh\theta_2}{1 \pm \tanh\theta_1\tanh\theta_2}; \quad \coth(\theta_1 \pm \theta_2) = \frac{1 \pm \coth\theta_1\coth\theta_2}{\coth\theta_1 \pm \coth\theta_2}$$

$$\sinh 2\theta = 2\sinh\theta\cosh\theta = \frac{2\tanh\theta}{1-\tanh^2\theta}$$

$$\cosh 2\theta = \sinh^2\theta + \cosh^2\theta = 1 + 2\sinh^2\theta = 2\cosh^2\theta - 1 = \frac{1+\tanh^2\theta}{1-\tanh^2\theta}$$

$$\tanh 2\theta = \frac{2\tanh\theta}{1+\tanh^2\theta}; \quad \coth 2\theta = \frac{1+\coth^2\theta}{2\coth\theta}$$

$$\sinh\theta/2 = \sqrt{(\cosh\theta - 1)/2}; \quad \cosh\theta/2 = \sqrt{(\cosh\theta + 1)/2}$$

$$\tanh\theta/2 = \sqrt{\frac{\cosh\theta - 1}{\cosh\theta + 1}} = \frac{\sinh\theta}{\cosh\theta + 1} = \frac{\cosh\theta - 1}{\sinh\theta}$$

$$\sinh\theta_1 \pm \sinh\theta_2 = 2\sinh\frac{(\theta_1 \pm \theta_2)}{2}\cosh\frac{(\theta_1 \mp \theta_2)}{2}$$

$$\cosh\theta_1 + \cosh\theta_2 = 2\cosh\frac{(\theta_1 + \theta_2)}{2}\cosh\frac{(\theta_1 - \theta_2)}{2}$$

$$\cosh\theta_1 - \cosh\theta_2 = 2\sinh\frac{(\theta_1 + \theta_2)}{2}\sinh\frac{(\theta_1 - \theta_2)}{2}$$

$$\tanh\theta_1 \pm \tanh\theta_2 = \frac{\sinh(\theta_1 \pm \theta_2)}{\cosh\theta_1\cosh\theta_2}:$$

$$(\cosh\theta \pm \sinh\theta)^n = \cosh n\theta \pm \sinh n\theta$$

Anti-hyperbolic or Inverse Functions. The angle whose hyperbolic sine is u is written: $\sinh^{-1} u$. Values of the angles in hyperbolic radians, corresponding to the several functions, may be computed from their logarithmic equivalents.

$$\sinh^{-1} u = \log_e (u + \sqrt{u^2+1}); \quad \cosh^{-1} u = \log_e (u + \sqrt{u^2-1})$$

$$\tanh^{-1} u = 1/2 \log_e \frac{1+u}{1-u}; \quad \coth^{-1} u = 1/2 \log_e \frac{u+1}{u-1}$$

28. FUNCTIONS OF IMAGINARY AND COMPLEX ANGLES

Relation of Hyperbolic to Circular Functions. By comparison of the exponential equivalents of hyperbolic and circular functions the following identities are established ($i = \sqrt{-1}$):

$\sin\alpha = -i\sinh i\alpha \qquad \sinh\beta = -i\sin i\beta$

$\cos\alpha = \cosh i\alpha \qquad \cosh\beta = \cos i\beta$

$\tan\alpha = -i\tanh i\alpha \qquad \tanh\beta = -i\tan i\beta$

$\cot\alpha = i\coth i\alpha \qquad \coth\beta = i\cot i\beta$

$\sec\alpha = \operatorname{sech} i\alpha \qquad \operatorname{sech}\beta = \sec i\beta$

$\csc\alpha = i\operatorname{csch} i\alpha \qquad \operatorname{csch}\beta = i\csc i\beta$

Relations between Inverse Functions.

$\sin^{-1} A = -i\sinh^{-1} i A \qquad \sinh^{-1} B = -i\sin^{-1} i B$

$\cos^{-1} A = -i\cosh^{-1} A \qquad \cosh^{-1} B = i\cos^{-1} B$

$\tan^{-1} A = -i\tanh^{-1} i A \qquad \tanh^{-1} B = -i\tan^{-1} i B$

$\cot^{-1} A = i\coth^{-1} i A \qquad \coth^{-1} B = i\cot^{-1} i B$

$\sec^{-1} A = -i\operatorname{sech}^{-1} A \qquad \operatorname{sech}^{-1} B = i\sec^{-1} B$

$\csc^{-1} A = i\operatorname{csch}^{-1} i A \qquad \operatorname{csch}^{-1} B = i\csc^{-1} i B$

Functions of a Complex Angle. In complex notation $c = a + ib = |c|(\cos\theta + i\sin\theta) = |c|\,e^{i\theta}$, where $|c| = \sqrt{a^2+b^2}$, $i = \sqrt{-1}$, and $\theta = \tan^{-1}\frac{b}{a}$. $|c|\,e^{i\theta}$, is frequently written $c\angle\theta$.

$\operatorname{Log}_e |c|\,e^{i\theta} = \log|c| + i(\theta + 2k\pi)$ and is infinitely many valued. By its principal part will be understood $\log_e |c| + i\theta$. Some convenient identities are:

$$\log_e 1 = 0; \quad \log_e(-1) = i\pi; \quad \log_e i = i\frac{\pi}{2}; \quad \log_e(-i) = i\frac{3\pi}{2}$$

$$(\cos\theta \pm i\sin\theta)^n = \cos n\theta \pm i\sin n\theta; \quad \sqrt[n]{\cos\theta \pm i\sin\theta} = \cos\frac{\theta + 2\pi k}{n} \pm i\sin\frac{\theta + 2\pi k}{n}$$

The use of complex angles occurs frequently in electric circuit problems where it is often necessary to express the functions of them as a complex number.

$$\sin(\alpha \pm i\beta) = \sin\alpha\cosh\beta \pm i\cos\alpha\sinh\beta = \sqrt{\cosh^2\beta - \cos^2\alpha}\,e^{\pm i\theta}$$

where $\theta = \tan^{-1}\cot\alpha\tanh\beta$.

$$\cos(\alpha \pm i\beta) = \cos\alpha \cosh\beta \mp i \sin\alpha \sinh\beta = \sqrt{\cosh^2\beta - \sin^2\alpha}\, e^{\pm i\theta}$$

where $\theta = \tan^{-1} \tan\alpha \tanh\beta$.

$$\sinh(\alpha \pm i\beta) = \sinh\alpha \cos\beta \pm i \cosh\alpha \sin\beta = \sqrt{\sinh^2\alpha + \sin^2\beta}\, e^{\pm i\theta} = \sqrt{\cosh^2\alpha - \cos^2\beta}\, e^{\pm i\theta}$$

where $\theta = \tan^{-1} \coth\alpha \tan\beta$.

$$\cosh(\alpha \pm i\beta) = \cosh\alpha \cos\beta \pm i \sinh\alpha \sin\beta = \sqrt{\sinh^2\alpha + \cos^2\beta}\, e^{\pm i\theta} = \sqrt{\cosh^2\alpha - \sin^2\beta}\, e^{\pm i\theta}$$

where $\theta = \tan^{-1} \tanh\alpha \tan\beta$.

$$\tan(\alpha \pm i\beta) = \frac{\sin 2\alpha \pm i \sinh 2\beta}{\cos 2\alpha + \cosh 2\beta}; \qquad \tanh(\alpha \pm i\beta) = \frac{\sinh 2\alpha \pm i \sin 2\beta}{\cosh 2\alpha + \cos 2\beta}$$

The hyperbolic sine and cosine have the period $2\pi i$; the hyperbolic tangent has the period πi.

$$\sinh(\alpha + 2k\pi i) = \sinh\alpha; \quad \cosh(\alpha + 2k\pi i) = \cosh\alpha$$

$$\tanh(\alpha + k\pi i) = \tanh\alpha; \quad \coth(\alpha + k\pi i) = \coth\alpha$$

Inverse Functions of Complex Numbers.

$$\sin^{-1}(A \pm iB) = \sin^{-1}\left[\frac{\sqrt{B^2 + (1 + A)^2} - \sqrt{B^2 + (1 - A)^2}}{2}\right]$$

$$\pm i \cosh^{-1}\left[\frac{\sqrt{B^2 + (1 + A)^2} + \sqrt{B^2 + (1 - A)^2}}{2}\right]$$

$$\cos^{-1}(A \pm iB) = \cos^{-1}\left[\frac{\sqrt{B^2 + (1 + A)^2} - \sqrt{B^2 + (1 - A)^2}}{2}\right]$$

$$\mp i \cosh^{-1}\left[\frac{\sqrt{B^2 + (1 + A)^2} + \sqrt{B^2 + (1 - A)^2}}{2}\right]$$

$$\tan^{-1}(A \pm iB) = \left[\frac{\pi - \tan^{-1}\dfrac{A}{\pm B - 1} + \tan^{-1}\dfrac{A}{\pm B + 1}}{2}\right]$$

$$\pm i\, {}^1/_4 \log_e \frac{A^2 + (1 \pm B)^2}{A^2 + (1 \mp B)^2}$$

$$\sinh^{-1}(A \pm iB) = \cosh^{-1}\left[\frac{\sqrt{A^2 + (1 + B)^2} + \sqrt{A^2 + (1 - B)^2}}{2}\right]$$

$$\pm i \sin^{-1}\left[\frac{\sqrt{A^2 + (1 + B)^2} - \sqrt{A^2 + (1 - B)^2}}{2}\right]$$

$$\cosh^{-1}(A \pm iB) = \cosh^{-1}\left[\frac{\sqrt{B^2 + (1 + A)^2} + \sqrt{B^2 + (1 - A)^2}}{2}\right]$$

$$\pm i \cos^{-1}\left[\frac{\sqrt{B^2 + (1 + A)^2} - \sqrt{B^2 + (1 - A)^2}}{2}\right]$$

$$\tanh^{-1}(A \pm iB) = {}^1/_2 \tanh^{-1}\frac{2A}{1 + A^2 + B^2} + i\, {}^1/_2 \tan^{-1}\frac{\pm 2B}{1 - A^2 - B^2}$$

PLANE ANALYTIC GEOMETRY

By M. J. Fish

29. POINT AND LINE

Coordinates. The position of a point P_1 in a plane is determined if its distance and direction from each of two lines or axes OX and OY, which are perpendicular to each other, are known. The distances x and y (Fig. 1) perpendicular to the axes are called the *cartesian* or *rectangular coordinates* of the point. The directions to the right of OY and above OX are called *positive*, and opposite directions *negative*. The point O of intersection of OY and OX is called the *origin*.

The position of a point P is also given by its radial distance r from the origin and the angle θ between the radius r and the horizontal axis OX (Fig. 2). These coordinates r, θ, are called *polar coordinates*.

The functional relation between the coordinates of any point on a line is the equation of the line and defines its character.

The distance s between two points P_1 (x_1, y_1) and P_2 (x_2, y_2) on a straight line is

$$s = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} \qquad (1)$$

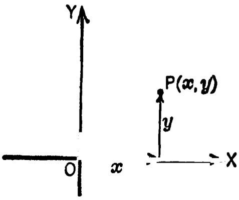

Fig 1

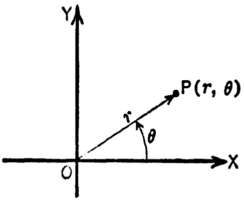

Fig. 2

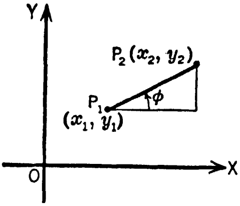

Fig. 3

The slope m of the line P_1P_2 is defined as the tangent of the angle ϕ, which the line makes with OX.

$$m = \tan \phi = \frac{y_2 - y_1}{x_2 - x_1} \qquad (2)$$

If expressed in polar coordinates

$$s = \sqrt{r_1^2 + r_2^2 - 2r_1 r_2 \cos (\theta_2 - \theta_1)} \qquad (3)$$

where r_1, r_2 and θ_1, θ_2 are the radius vectors and vectorial angles of the points P_1 and P_2.

The Equation of a Straight Line in cartesian coordinates is of the first degree and is expressed as follows:

$$Ax + By + C = 0 \qquad (4)$$

where A, B, and C are constants.

Other forms of the equation are:

$$y = mx + b \qquad (5)$$

where m is the slope and b is the y intercept;

$$y - y_1 = m(x - x_1) \qquad (6)$$

where m is the slope and (x_1, y_1) is a point on the line;

$$\frac{x - x_1}{y - y_1} = \frac{x_1 - x_2}{y_1 - y_2} \qquad (7)$$

where (x_1, y_1) and (x_2, y_2) are two points on the line;

$$\frac{x}{a} + \frac{y}{b} = 1 \qquad (8)$$

where a and b are the x and y intercepts, respectively;

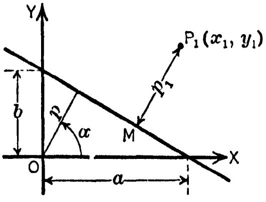

Fig. 4

$$x \cos \alpha + y \sin \alpha - p = 0 \qquad (9)$$

where α is the angle between OX and the perpendicular from the origin to the line and p is the length of the perpendicular (Fig. 4). This is called the *perpendicular* form and is obtained by dividing the general form $Ax + By + C = 0$ by $\pm \sqrt{A^2 + B^2}$. The sign before the radical is taken opposite to that of C if $C \neq 0$ and the same as that of B if $C = 0$.

The Perpendicular Distance of a Point P_1 (x_1, y_1) (Fig. 4) from the line $Ax + By + C = 0$ is

$$p_1 = \frac{Ax_1 + By_1 + C}{\pm \sqrt{A^2 + B^2}} \qquad (10)$$

where the sign before the radical is opposite to that of C if $C \neq 0$, and the same as B if $C = 0$.

Parallel Lines. The two lines $Ax + By + C = 0$, $A_1x + B_1y + C_1 = 0$ are parallel if

$$\frac{A}{A_1} = \frac{B}{B_1} \qquad (11)$$

A line through the point (x_1, y_1) and parallel to the line $Ax + By + C = 0$ has the equation

$$A(x - x_1) + B(y - y_1) = 0 \tag{12}$$

If the two equations are written as $y = m_1x + b_1$, $y = m_2x + b_2$, the lines are parallel if $m_1 = m_2$.

Perpendicular Lines. The two lines $y = m_1x + b_1$ and $y = m_2x + b_2$ are perpendicular if

$$m_1 = -\frac{1}{m_2} \tag{13}$$

If the equations are written as $Ax + By + C = 0$, $A_1x + B_1y + C_1 = 0$, the lines are perpendicular if

$$AA_1 + BB_1 = 0 \tag{14}$$

A line through the point (x_1, y_1) perpendicular to the line $Ax + By + C = 0$ has the equation

$$B(x - x_1) - A(y - y_1) = 0 \tag{15}$$

Intersecting Lines. Let $Ax + By + C = 0$ and $A_1x + B_1y + C_1 = 0$ be the equations of two intersecting lines and λ an arbitrary constant. Then

$$(Ax + By + C) + \lambda(A_1x + B_1y + C_1) = 0 \tag{16}$$

represents the system of lines through the point of intersection.

The three lines $Ax + By + C = 0$, $A_1x + B_1y + C_1 = 0$, $A_2x + B_2x + C_2 = 0$ meet in a point if

$$\begin{vmatrix} A & B & C \\ A_1 & B_1 & C_1 \\ A_2 & B_2 & C_2 \end{vmatrix} = 0 \tag{17}$$

The Angle θ between Two Lines with equations $A_1x + B_1y + C_1 = 0$ and $A_2x + B_2y + C_2 = 0$ can be found from

$$\sin\theta = \frac{A_1B_2 - A_2B_1}{\sqrt{(A_1^2+B_1^2)(A_2^2+B_2^2)}},\ \cos\theta = \frac{A_1A_2 + B_1B_2}{\sqrt{(A_1^2+B_1^2)(A_2^2+B_2^2)}},\ \tan\theta = \frac{A_1B_2 - A_2B_1}{A_1A_2 + B_1B_2} \tag{18}$$

The signs of $\tan\theta$ and $\cos\theta$ determine whether the acute or obtuse angle is meant. If the equations are in the form $y = m_1x + b_1$, $y = m_2x + b_2$, then

$$\sin\theta = \frac{m_2 - m_1}{\sqrt{(1 + m_1^2)(1 + m_2^2)}},\ \cos\theta = \frac{1 + m_1m_2}{\sqrt{(1 + m_1^2)(1 + m_2^2)}},\ \tan\theta = \frac{m_2 - m_1}{1 + m_1m_2} \tag{19}$$

30. TRANSFORMATION OF COORDINATES

Change of Origin O to O′. Let x, y denote the coordinates of a point P with respect to the old axes, and x', y' the coordinates with respect to the new axes (Fig. 5). Then, if the coordinates of the new origin O' with respect to the old axes are $x = h$, $y = k$, the relations between the old and the new coordinates are

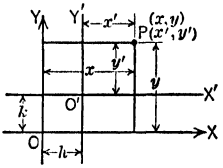

Fig. 5

$$\left.\begin{aligned} x &= x' + h, \\ y &= y' + k \end{aligned}\right\} \tag{20}$$

Rotation of Axes about the Origin. Let θ (Fig. 6) be the angle through which the axes are rotated. Then

$$\left.\begin{aligned} x &= x'\cos\theta - y'\sin\theta \\ y &= x'\sin\theta + y'\cos\theta \end{aligned}\right\} \tag{21}$$

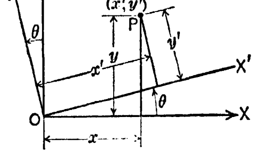

Fig. 6

If the axes are both translated and rotated,

$$\left.\begin{aligned} x &= x'\cos\theta - y'\sin\theta + h \\ y &= x'\sin\theta + y'\cos\theta + k \end{aligned}\right\} \tag{22}$$

Coordinate Transformation. The relations between the rectangular coordinates x, y and the polar coordinates r, θ are

$$x = r\cos\theta,\ y = r\sin\theta,\ r = \sqrt{x^2 + y^2},\ \theta = \tan^{-1}\frac{y}{x} \tag{23}$$

$$x + iy = r\,e^{i\theta},\ x - iy = r\,e^{-i\theta} \tag{24}$$

($i = \sqrt{-1}$, $e = 2.7183$, the base of the natural logarithms)

31. CONIC SECTIONS

A Conic Section is a curve traced by a point P moving in a plane so that the distance PF of the point from a fixed point (*focus*) is in constant ratio to the distance PM of the point from a fixed line (*directrix*) in the plane of the curve. The ratio, $e = \frac{PF}{PM}$, is called the *eccentricity*. If $e < 1$, the curve is an *ellipse*; $e = 1$, a *parabola*; $e > 1$, an *hyperbola*; and $e = 0$, a *circle*, which is a special case of an ellipse.

The Circle. The equation is

$$(x - x_0)^2 + (y - y_0)^2 = r^2 \tag{25}$$

where (x_0, y_0) is the center and r the radius. If $x_0 = 0$, $y_0 = 0$, that is, if the center is at the origin,

$$x^2 + y^2 = r^2 \tag{26}$$

If the point $P_1(x_1, y_1)$ is on the circle $x^2 + y^2 + 2gx + 2fy + c = 0$, then the equation of the tangent to the circle at $P_1(x_1, y_1)$ is

$$xx_1 + yy_1 + g(x + x_1) + f(y + y_1) + c = 0 \tag{27}$$

The Ellipse (Fig. 7). The equation is

$$\frac{(x - x_0)^2}{a^2} + \frac{(y - y_0)^2}{b^2} = 1 \tag{28}$$

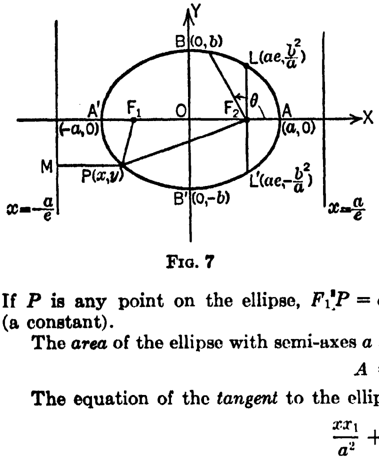

Fig. 7

where (x_0, y_0) is the center, a = semi-major axis, b = semi-minor axis. In Fig. 7, $(x_0, y_0) = (0, 0)$.

Coordinates of *foci* are $F_1 = (-ae, 0)$, $F_2 = (ae, 0)$; $e^2 = \frac{(F_1P)^2}{(MP)^2} = 1 - \frac{b^2}{a^2} < 1$; and the *directrices* are the lines $x = -\frac{a}{e}$, $x = \frac{a}{e}$.

The chord LL' through F is called the *latus rectum* and has the length $\frac{2b^2}{a} = 2a\,(1 - e^2)$.

If P is any point on the ellipse, $F_1P = a - ex$, $F_2P = a + ex$, and $F_1P + F_2P = 2a$ (a constant).

The *area* of the ellipse with semi-axes a and b is

$$A = \pi ab \tag{29}$$

The equation of the *tangent* to the ellipse at the point (x_1, y_1) is

$$\frac{xx_1}{a^2} + \frac{yy_1}{b^2} = 1; \tag{30}$$

the equation of the tangent with slope m is

$$y = mx \pm \sqrt{a^2m^2 + b^2} \tag{31}$$

The equation of the *normal* to the ellipse at the point (x_1, y_1) is

$$(x - x_1)\frac{y_1}{b^2} - (y - y_1)\frac{x_1}{a^2} = 0 \tag{32}$$

Conjugate Diameters. A line through the center of an ellipse is a *diameter*; if the slopes m and m' of the two diameters $y = mx$ and $y = m'x$ are such that $mm' = -\frac{b^2}{a^2}$ each diameter bisects all chords parallel to the other and the diameters are called *conjugate*.

Other Forms of the Equation of the Ellipse.

$$\frac{x^2}{a^2} + \frac{y^2}{a^2(1 - e^2)} = 1 \tag{33}$$

$$ax^2 + by^2 + 2gx + 2fy + c = 0 \tag{34}$$

If a, b, and $\left(\frac{g^2}{a} + \frac{f^2}{b} - c\right)$ have the same sign, (34) is an ellipse whose axes are parallel to the coordinate axes.

The polar form of the equation with F_2 as pole and F_2A as the polar axis is

$$r = \frac{a(1 - e^2)}{1 - e\cos\theta} \tag{35}$$

The parametric form is

$$x = a\cos\phi,\ y = b\sin\phi \tag{36}$$

The Hyperbola (Fig. 8). The equation is

$$\frac{(x - x_0)^2}{a^2} - \frac{(y - y_0)^2}{b^2} = 1 \tag{37}$$

where (x_0, y_0) is the center, $AA' = 2a$ is the transverse axis, $BB' = 2b$ is the conjugate axis. In Fig. 8, $(x_0, y_0) = (0, 0)$.

$e^2 = \frac{(F_1P)^2}{(PM)^2} = 1 + \frac{b^2}{a^2} > 1$; the coordinates of the *foci*, $F_1 = (-ae, 0)$, $F_2 = (ae, 0)$; and the *directrices* are the lines $x = -\frac{a}{e}$, $x = \frac{a}{e}$.

The chord LL' through F is called the *latus rectum* and has the length $\frac{2b^2}{a}$. If P is any point on the curve, $F_1P = ex - a$, $F_2P = ex + a$, and $|F_2P - F_1P| = 2a$ (a constant).

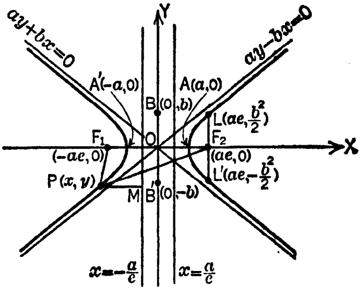

FIG. 8

The equation of the *tangent* to the hyperbola at the point (x_1, y_1) is

$$\frac{xx_1}{a^2} - \frac{yy_1}{b^2} = 1 \tag{38}$$

The equation of the tangent whose slope is m is

$$y = mx \pm \sqrt{a^2m^2 - b^2} \tag{39}$$

The equation of the *normal* to the hyperbola at the point (x_1, y_1) is

$$a^2y_1(x - x_1) + b^2x_1(y - y_1) = 0 \tag{40}$$

Conjugate Hyperbolas and Diameters. The two hyperbolas $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$ and $\frac{y^2}{b^2} - \frac{x^2}{a^2} = 1$ are conjugate. The transverse axis of each is the conjugate axis of the other.

If the slopes of the two lines $y = mx$ and $y = m_1x$ through the center O are connected by the relation $mm_1 = \frac{b^2}{a^2}$, each of these lines bisects all chords of the hyperbola which are parallel to the other line. Two such lines are called *conjugate diameters.* The equation of the hyperbola referred to its conjugate diameters as oblique axes is

$$\frac{x'^2}{a_1^2} - \frac{y'^2}{b_1^2} = 1 \tag{41}$$

where $2a_1$ and $2b_1$ are the conjugate axes.

The Asymptotes. The lines $y = \frac{b}{a}x$ and $y = -\frac{b}{a}x$ are the *asymptotes* of the hyperbola $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$. The asymptotes are two tangents whose points of contact with the curve are at an infinite distance from the center. The equation of the hyperbola when referred to its asymptotes as oblique axes is

$$4x'y' = a^2 + b^2 \tag{42}$$

If $a = b$, the asymptotes are the perpendicular lines $y = x$, $y = -x$; the corresponding hyperbola

$$x^2 - y^2 = a^2 \tag{43}$$

is called the *rectangular* or *equilateral hyperbola.*

The Parabola (Fig. 9). The equation of the parabola is

$$y^2 = 4ax \tag{44}$$

The *focus* F is on OX, called the *axis of the parabola,* and has the coordinates $(a, 0)$; the *eccentricity* $e = \frac{FP}{PM} = 1$; and the *directrix* is $x = -a$. The chord LL' through F is the *latus rectum* and has the length $4a$.

The *tangent* to the parabola $y^2 = 4ax$ at the point (x_1, y_1) is

$$yy_1 = 2a(x + x_1) \tag{45}$$

The equation of the tangent whose slope is m is

$$y = mx + \frac{a}{m} \tag{46}$$

The *normal* to the parabola at the point (x_1, y_1) is

$$2a(y - y_1) + y_1(x - x_1) = 0 \tag{47}$$

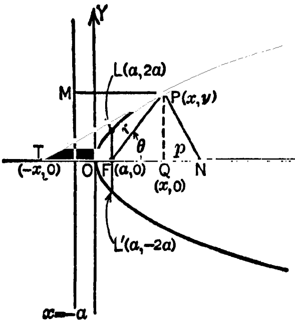

Fig. 9

A *diameter* of the curve is a straight line parallel to the axis. It bisects all chords parallel to the tangent at the point where the diameter meets the parabola.

If P_1T is tangent to the curve at (x_1, y_1), then $TQ = 2x_1$ is the *subtangent*, and $QN = 2a$ (a constant) is the *subnormal*, where P_1N is perpendicular to P_1T.

The equation of the form $y^2 + 2gx + 2fy + c = 0$, where $g \neq 0$, is a parabola whose axis is parallel to OX; and the equation $x^2 + 2gx + 2fy + c = 0$, where $f \neq 0$, is a parabola whose axis is parallel to OY.

The polar equation of the parabola with F as pole and FO as polar axis is

$$r = \frac{p}{1 - \cos\theta} \tag{48}$$

where p is one-half the latus rectum ($p = 2a$ in Fig. 9).

The parabola referred to the tangents at the extremities of its latus rectum as axes of coordinates is

$$x^{1/2} \pm y^{1/2} = b^{1/2} \tag{49}$$

where b is the distance from the origin to each point of tangency.

The General Equation of a Conic Section has the form

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c = 0 \tag{50}$$

$$\text{Let } D = \begin{vmatrix} a & h & g \\ h & b & f \\ g & f & c \end{vmatrix}; \quad d = \begin{vmatrix} a & h \\ h & b \end{vmatrix} \tag{51}$$

Then the following is a classification of conic sections.

1. Two parallel lines, for $D = 0$, $d = 0$.
2. Two intersecting lines, for $D = 0$, $d \neq 0$.
3. A parabola, for $D \neq 0$, $d = 0$.
4. An ellipse, for $D \neq 0$, $d > 0$ (central conic).
5. An hyperbola, for $D \neq 0$, $d < 0$ (central conic).

Let $A + B = a + b$, $AB = ab - h^2 = d$, and $A - B$ have the same sign as h. Let $c' = D/d$; then the equation of the conic referred to its axes is

$$\frac{x^2}{-\frac{c'}{A}} + \frac{y^2}{-\frac{c'}{B}} = 1 \tag{52}$$

To find the center (x_0, y_0) of the conic solve the equations

$$\left.\begin{aligned} ax_0 + hy_0 + g &= 0 \\ hx_0 + by_0 + f &= 0 \end{aligned}\right\} \tag{53}$$

To remove the term in xy from (50), rotate the axes about the origin through an angle θ such that $\tan 2\theta = \dfrac{2h}{a - b}$.

32. HIGHER PLANE CURVES

Plane Curves. The point (x, y) describes a plane curve if x and y are continuous functions of a variable t (parameter), as $x = x(t)$, $y = y(t)$. The elimination of t from the two equations gives $F(x, y) = 0$ or in explicit form $y = f(x)$. The angle τ which the tangent to the curve makes with OX can be found from

$$\sin \tau = \frac{dy}{ds}, \quad \cos \tau = \frac{dx}{ds}, \quad \tan \tau = \frac{dy}{dx} = y' \tag{54}$$

where ds is the element of arc length:

$$ds = \sqrt{dx^2 + dy^2} = \sqrt{1 + y'^2}\, dx > 0 \tag{55}$$

In polar coordinates,

$$ds = \sqrt{dr^2 + r^2 d\theta^2} = \sqrt{\left(\frac{dr}{d\theta}\right)^2 + r^2}\, d\theta \tag{56}$$

From Fig. 10, it may be seen that

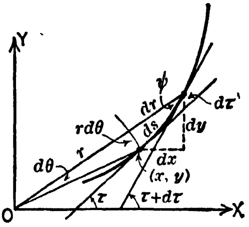

FIG. 10

$$\sin \psi = \frac{r d\theta}{ds}, \quad \cos \psi = \frac{dr}{ds}, \quad \tan \psi = \frac{r d\theta}{dr} \tag{57}$$

The equation of the *tangent* to the curve $F(x, y) = 0$ at the point (x_1, y_1) is

$$\left(\frac{\partial F}{\partial x}\right)_{x = x_1,\, y = y_1} (x - x_1) + \left(\frac{\partial F}{\partial y}\right)_{x = x_1,\, y = y_1} (y - y_1) = 0 \tag{58}$$

The equation of the *normal* to the curve $F(x, y) = 0$ at the point (x_1, y_1) is

$$\left(\frac{\partial F}{\partial y}\right)_{x = x_1,\, y = y_1} (x - x_1) - \left(\frac{\partial F}{\partial x}\right)_{x = x_1,\, y = y_1} (y - y_1) = 0 \tag{59}$$

The *radius of curvature* of the curve at the point (x, y) is

$$\rho = \frac{ds}{d\tau} = \frac{\left[1 + \left(\frac{dy}{dx}\right)^2\right]^{3/2}}{\frac{d^2y}{dx^2}} = \frac{[1 + y'^2]^{3/2}}{y''} \tag{60}$$

The reciprocal $1/\rho$ is called the *curvature of the curve* at (x, y).

The coordinates (x_0, y_0) of the center of curvature for the point (x, y) on the curve (the center of the circle of curvature tangent to the curve at (x, y) and of radius ρ) can be found from the equations

$$\left.\begin{aligned} x_0 &= x - \rho \frac{dy}{ds} = x - y' \frac{[1 + y'^2]}{y''} \\ y_0 &= y + \rho \frac{dx}{ds} = y + \frac{[1 + y'^2]}{y''} \end{aligned}\right\} \tag{61}$$

A curve has a *singular point* if simultaneously,

$$F(x, y) = 0, \quad \frac{\partial F}{\partial x} = 0, \quad \frac{\partial F}{\partial y} = 0 \tag{62}$$

Let

$$D = \left(\frac{\partial^2 F}{\partial x \partial y}\right)^2 - \frac{\partial^2 F}{\partial x^2} \frac{\partial^2 F}{\partial y^2} \tag{63}$$

Then for $D > 0$, the curve has a *double point* with two real different tangents.

For $D = 0$, the curve has a *cusp* with two coincident tangents.

For $D < 0$, the curve has an *isolated point* with no real tangent.

Cycloid and Trochoid. A *cycloid* is a curve traced by a point P on the circumference of a circle which rolls without slipping on a straight line (Fig. 11). The parametric equations are

$$x = OD = a(\phi - \sin \phi), \quad y = DP = a(1 - \cos \phi) \tag{64}$$

In rectangular coordinates

$$x = a\cos^{-1}\frac{(a-y)}{a} \pm \sqrt{(2a-y)y} \tag{65}$$

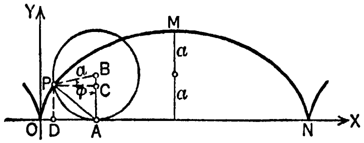

FIG. 11

The length of one arch of the cycloid is

$$s = 8a \tag{66}$$

and its area

$$A = 3\pi a^2 \tag{67}$$

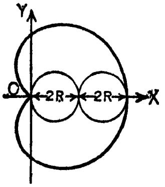

FIG. 12

A point on the radius at a distance $b > a$ from the center describes a *prolate trochoid.* A point at a distance $b < a$ describes a *curtate trochoid.* The general equations for cycloids and trochoids are

$$x = a\phi - b\sin\phi,\quad y = b(1-\cos\phi) \tag{68}$$

If $a = b$, the figure is a cycloid; if $b > a$, prolate trochoid; if $b < a$, curtate trochoid.

Epicycloid and Hypocycloid. An *epicycloid* is a curve traced by a point on the circumference of a circle of radius r which rolls without slipping on the outside of a fixed circle of radius R. If the moving circle rolls without slipping on the inside of the fixed circle, the curve is an *hypocycloid.*

An epicycloid has the equations

$$\left.\begin{aligned} x &= (R+r)\cos\phi - r\cos\frac{R+r}{r}\phi \\ y &= (R+r)\sin\phi - r\sin\frac{R+r}{r}\phi \end{aligned}\right\} \tag{69}$$

For $r = R$, the epicycloid becomes a *cardioid* (Fig. 12) with the equation

$$(x^2 + y^2 - 2Rx)^2 = 4R^2(x^2 + y^2) \tag{70}$$

or in polar coordinates

$$r = 2R\,(1 + \cos\theta) \tag{71}$$

An hypocycloid has the equations

$$\left.\begin{aligned} x &= (R-r)\cos\phi + r\cos\frac{R-r}{r}\phi \\ y &= (R-r)\sin\phi - r\sin\frac{R-r}{r}\phi \end{aligned}\right\} \tag{72}$$

For $r = \frac{1}{4}R$, the rolling circle makes four revolutions in passing around the fixed circle forming the *astroid* or hypocycloid of four cusps with equation

$$x^{2/3} + y^{2/3} = R^{2/3} \tag{73}$$

An Epitrochoid is a curve traced by a point on the radius of the outer rolling circle at a fixed distance b from its center. The equations of the curve are

$$\left.\begin{aligned} x &= (R+r)\cos\phi - b\cos\frac{R+r}{r}\phi \\ y &= (R+r)\sin\phi - b\sin\frac{R+r}{r}\phi \end{aligned}\right\} \tag{74}$$

An Hypotrochoid is a curve traced by a point on the radius of the inner rolling circle at a fixed distance b from its center. The equations are

$$\left.\begin{aligned} x &= (R-r)\cos\phi + b\cos\frac{R-r}{r}\phi \\ y &= (R-r)\sin\phi - b\sin\frac{R-r}{r}\phi \end{aligned}\right\} \tag{75}$$

If $R = 2r$, the hypotrochoid is an ellipse.

An Involute of a Circle is a curve traced by the end of a taut string wrapped around a fixed circle and unwinding (Fig. 13). If it begins to unwind at A, the arc AP of the involute is traced when the string has unwound as far as B, and the part unwound is BP. BP is tangent to the circle at B and BP = arc $BA = r\phi$. The parametric equations are

$$\left.\begin{aligned} x &= R\cos\phi + R\,\phi\sin\phi \\ y &= R\sin\phi - R\,\phi\cos\phi \end{aligned}\right\} \tag{76}$$

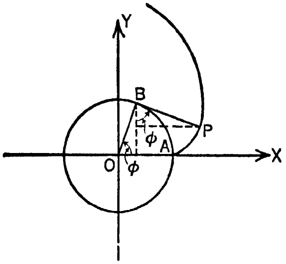

FIG. 13

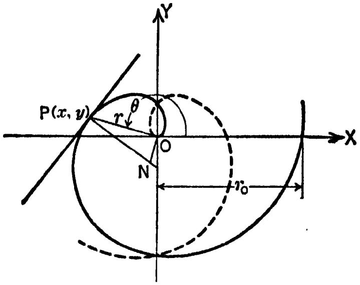

FIG. 14

A Spiral of Archimedes is the locus of a point P whose distance from the origin O is proportional to the angle which the radius vector OP makes with a fixed initial position (Fig. 14). Another method of finding the curve is to consider it generated by a point P moving at a constant speed in a given straight line OP, which at the same time rotates at constant speed about a fixed point O on the line. The equation is

$$r = a\theta \tag{77}$$

where $a = ON$ (a constant), the polar subnormal.

After one complete turn of OP, the length OP is $r_0 = 2\pi a$, and after $1/n$ turns, its length is $r = r_0/n$. The length of the arc OP is

$$s = {}^1\!/_2\, a\left[\theta\sqrt{1+\theta^2} + \sinh^{-1}\theta\right] \qquad (77)$$

For many turns it is approximately

$$s \approx {}^1\!/_2\, a\,\theta^2 \tag{78}$$

An Hyperbolic Spiral has the equation

$$r\theta = a \tag{79}$$

where $OT = -a$ (a constant), the polar subtangent (Fig. 15). If $\theta \to \infty$, then $r \to 0$. Therefore, the origin is an asymptotic point about which the curve winds an infinite number of times but which it never actually reaches.

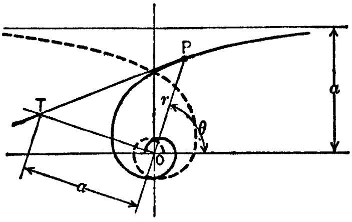

FIG. 15

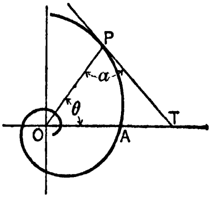

FIG. 16

If $\theta \to 0$, $r \to \infty$. Therefore, a line parallel to the polar axis at a distance a is an asymptote of the curve.

A Logarithmic or Equiangular Spiral is a curve that makes a constant angle with the radius vectors (Fig. 16.). Its polar equation is

$$r = ae^{m\theta} \qquad (m > 0) \tag{80}$$

For $\theta = 0$, $r = OA = a$; $m = \cot\alpha$, α being the constant angle.

As $\theta \to -\infty$, $r \to 0$. Therefore, the origin is an asymptotic point, which, for decreasing θ, the spiral approaches but never actually reaches.

A Lemniscate is the locus of a point P, the product of whose distances r_1 and r_2 from two fixed points F_1 and F_2 is a constant (Fig. 17). Let $r_1^2 \cdot r_2^2 = c^4$; then the equation of the lemniscate is

$$(x^2 + y^2)^2 + 2\,c^2(y^2 - x^2) = 0 \tag{81}$$

or in polar coordinates

$$r^2 = 2\,c^2 \cos 2\theta \tag{82}$$

The coordinates of F_1 are $(c, 0)$, and F_2 are $(-\,c, 0)$.

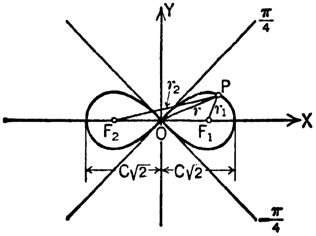

Fig. 17

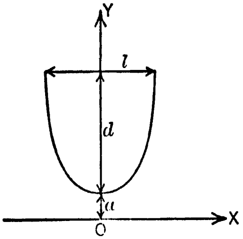

Fig. 18

A Catenary is a curve made by a cord of uniform weight suspended freely between two points at the same level (Fig. 18). Its equation is

$$y = \frac{a}{2}\,(e^{x/a} + e^{-x/a}) \tag{83}$$

The length of arc s is approximately equal to $l\left[1 + \frac{2}{3}\left(\frac{2d}{l}\right)^2\right]$, for l large in comparison to d.

SOLID ANALYTIC GEOMETRY

By M. J. Fish

33. POINT, LINE, AND PLANE

Coordinates. In a right-hand orthogonal cartesian coordinate system the position of a point P (Fig. 1) is fixed by its distance and direction from each of three planes which are perpendicular to each other. Thus the coordinates of the point P (x, y, z) are the perpendicular distances to the planes zy, xz, and xy, respectively.

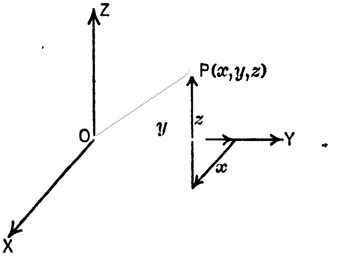

Fig. 1

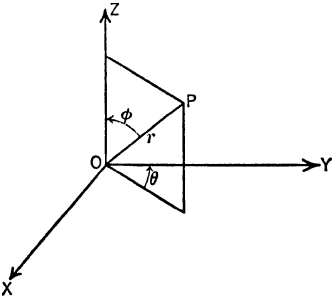

Fig. 2

The position of a point in space is also determined by its distance and direction from some fixed point. In Fig. 2 the distance from the origin O is r, and the direction of r is fixed by the angles θ and ϕ. The three quantities, r, θ, ϕ, are called the *spherical* or polar coordinates, where r is the *radius vector* of the point and the angles θ and ϕ are the *vectorial angles.*

The Distance between Two Points, P_1 (x_1, y_1, z_1) and P_2 (x_2, y_2, z_2) is

$$s = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2} \tag{1}$$

The angles α β, γ, which the line $P_1 P_2$ makes with the coordinate directions X, Y, Z, respectively, are called the *direction angles* of $P_1 P_2$.

The cosines,

$$\cos \alpha = \frac{x_2 - x_1}{s}, \quad \cos \beta = \frac{y_2 - y_1}{s}, \quad \cos \gamma = \frac{z_2 - z_1}{s} \tag{2}$$

are called the *direction cosines* of $P_1 P_2$, and

$$\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1 \tag{3}$$

The Angle between Two Lines in terms of their direction angles α_1, β_1, γ_1, and α_2, β_2, γ_2, is obtained from the relation:

$$\cos \theta = \cos \alpha_1 \cos \alpha_2 + \cos \beta_1 \cos \beta_2 + \cos \gamma_1 \cos \gamma_2 \tag{4}$$

If $\cos \theta = 0$, $\theta = 90°$ and the lines are perpendicular to each other.

A Straight Line in Space is represented by the first degree equations,

$$\left.\begin{aligned} y &= m_1 x + b_1 \\ z &= m_2 x + b_2 \end{aligned}\right\} \tag{5}$$

If the line goes through a point $P_1(x_1, y_1, z_1)$ and has the direction angles α, β, γ, then

$$\frac{x - x_1}{\cos \alpha} = \frac{y - y_1}{\cos \beta} = \frac{z - z_1}{\cos \gamma} \tag{6}$$

and $m_1 = \dfrac{\cos \beta}{\cos \alpha}$, $m_2 = \dfrac{\cos \gamma}{\cos \alpha}$

The equations of a line through two points (x_1, y_1, z_1) and (x_2, y_2, z_2) are

$$\frac{x - x_1}{x_2 - x_1} = \frac{y - y_1}{y_2 - y_1} = \frac{z - z_1}{z_2 - z_1} \tag{7}$$

The Equation of a Plane may be expressed as follows:

$$Ax + By + Cz + D = 0 \tag{8}$$

where A, B, C, and D are constants.

$Ax + By + D = 0$, is a plane parallel to the z axis.

$Ax + Cz + D = 0$, is a plane parallel to the y axis.

$By + Cz + D = 0$, is a plane parallel to the x axis.

$Ax + By + Cz = 0$, is a plane passing through the origin O.

A plane through three points P_1 (x_1, y_1, z_1), P_2 (x_2, y_2, z_2), P_3 (x_3, y_3, z_3) has the equation

$$\begin{vmatrix} x & y & z & 1 \\ x_1 & y_1 & z_1 & 1 \\ x_2 & y_2 & z_2 & 1 \\ x_3 & y_3 & z_3 & 1 \end{vmatrix} = 0 \tag{9}$$

The equation of a plane whose x, y, z intercepts are respectively a, b, c (Fig. 3) is

$$\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1 \tag{10}$$

The perpendicular form of the equation of a plane, where $OP = p$ is the perpendicular distance of the plane from the origin O and has the direction angles α, β, γ, is

$$x \cos \alpha + y \cos \beta + z \cos \gamma - p = 0 \tag{11}$$

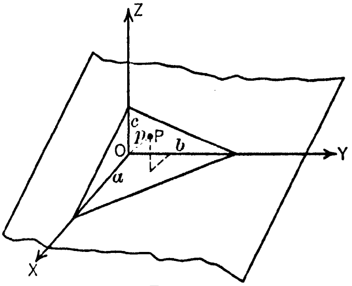

FIG. 3

To bring the general form $Ax + By + Cz + D = 0$ into the perpendicular form, divide it by $\pm \sqrt{A^2 + B^2 + C^2}$, where the sign before the radical is opposite to that of D.

The coefficients A, B, C are proportional to the direction cosines λ, μ, ν of a line perpendicular to the plane. Therefore,

$$A(x - x_1) + B(y - y_1) + C(z - z_1) = 0 \tag{12}$$

is a plane through P_1 (x_1, y_1, z_1) and perpendicular to a line with direction cosines λ, μ, ν proportional to A, B, C.

The Perpendicular Distance of a Point P_1 from a Plane $Ax + By + Cz + D = 0$ is given by

$$PP_1 = \frac{Ax_1 + By_1 + Cz_1 + D}{\pm \sqrt{A^2 + B^2 + C^2}} \tag{13}$$

where the sign before the radical is opposite to that of D.

A Line through a Point P_1 Perpendicular to a Plane $Ax + By + Cz + D = 0$ has the equations

$$\frac{x - x_1}{A} = \frac{y - y_1}{B} = \frac{z - z_1}{C} \tag{14}$$

Parallel Planes. Two planes $A_1x + B_1y + C_1z + D_1 = 0$ and $A_2x + B_2y + C_2z + D_2 = 0$ are parallel if $A_1 : B_1 : C_1 = A_2 : B_2 : C_2$.

$$A(x - x_1) + B(y - y_1) + C(z - z_1) = 0 \tag{15}$$

is a plane through the point P_1 (x_1, y_1, z_1) and parallel to the plane $Ax + By + Cz + D = 0$.

The Angle θ between Two Planes $Ax + By + Cz + D = 0$ and $A_1x + B_1y + C_1z + D_1 = 0$ is the angle between two intersecting lines, each perpendicular to one of the planes:

$$\cos\theta = \frac{AA_1 + BB_1 + CC_1}{\pm\sqrt{(A^2 + B^2 + C^2)(A_1^2 + B_1^2 + C_1^2)}} \tag{16}$$

The two planes are perpendicular if $AA_1 + BB_1 + CC_1 = 0$.

Line of Intersection of Two Planes. The direction cosines λ, μ, ν of the line of intersection of two planes $Ax + By + Cz + D = 0$ and $A_1x + B_1y + C_1z + D_1 = 0$ are found from the ratios

$$\lambda : \mu : \nu = \begin{vmatrix} B & C \\ B_1 & C_1 \end{vmatrix} : \begin{vmatrix} C & A \\ C_1 & A_1 \end{vmatrix} : \begin{vmatrix} A & B \\ A_1 & B_1 \end{vmatrix} \tag{17}$$

Four Points, P_k $(x_k, y_k, z_k)(k = 1, 2, 3, 4)$, lie in the same plane if

$$\begin{vmatrix} 1 & x_1 & y_1 & z_1 \\ 1 & x_2 & y_2 & z_2 \\ 1 & x_3 & y_3 & z_3 \\ 1 & x_4 & y_4 & z_4 \end{vmatrix} = 0 \tag{18}$$

Four Planes $A_k x + B_k y + C_k z + D_k = 0$ $(k = 1, 2, 3, 4)$ pass through the same point if

$$\begin{vmatrix} A_1 & B_1 & C_1 & D_1 \\ A_2 & B_2 & C_2 & D_2 \\ A_3 & B_3 & C_3 & D_3 \\ A_4 & B_4 & C_4 & D_4 \end{vmatrix} = 0 \tag{19}$$

34. TRANSFORMATION OF COORDINATES

Changing the Origin. Let the coordinates of a point P with respect to the original axes be x, y, z and with respect to the new axes x', y', z'. For a parallel displacement of the axes with x_0, y_0, z_0 the coordinates of the new origin

$$x = x_0 + x', \quad y = y_0 + y', \quad z = z_0 + z' \tag{20}$$

Rotation of the Axes about the Origin. Let the cosines of the angles of the new axes x', y', z', with the x axis be λ_1, μ_1, ν_1, with the y axis be λ_2, μ_2, ν_2, with the z axis be λ_3, μ_3, ν_3.

$$\left.\begin{aligned} \text{Then } x &= \lambda_1 x' + \mu_1 y' + \nu_1 z' & x' &= \lambda_1 x + \lambda_2 y + \lambda_3 z \\ y &= \lambda_2 x' + \mu_2 y' + \nu_2 z' & y' &= \mu_1 x + \mu_2 y + \mu_3 z \\ z &= \lambda_3 x' + \mu_3 y' + \nu_3 z' & z' &= \nu_1 x + \nu_2 y + \nu_3 z \end{aligned}\right\} \tag{21}$$

The following are the orthogonality conditions:

$$\begin{aligned}
&(1)\ \lambda_1^2 + \mu_1^2 + \nu_1^2 = 1 && (5)\ \lambda_1 = \mu_2\nu_3 - \nu_2\mu_3 \\
&\ \lambda_2^2 + \mu_2^2 + \nu_2^2 = 1 && \ \mu_1 = \nu_2\lambda_3 - \lambda_2\nu_3 \\
&\ \lambda_3^2 + \mu_3^2 + \nu_3^2 = 1 && \ \nu_1 = \lambda_2\mu_3 - \mu_2\lambda_3 \\
&(2)\ \lambda_1^2 + \lambda_2^2 + \lambda_3^2 = 1 && (6)\ \lambda_2 = \nu_1\mu_3 - \mu_1\nu_3 \\
&\ \mu_1^2 + \mu_2^2 + \mu_3^2 = 1 && \ \mu_2 = \lambda_1\nu_3 - \nu_1\lambda_3 \\
&\ \nu_1^2 + \nu_2^2 + \nu_3^2 = 1 && \ \nu_2 = \mu_1\lambda_3 - \lambda_1\mu_3 \\
&(3)\ \lambda_1\lambda_2 + \mu_1\mu_2 + \nu_1\nu_2 = 0 && (7)\ \lambda_3 = \mu_1\nu_2 - \nu_1\mu_2 \\
&\ \lambda_2\lambda_3 + \mu_2\mu_3 + \nu_2\nu_3 = 0 && \ \mu_3 = \nu_1\lambda_2 - \lambda_1\nu_2 \\
&\ \lambda_3\lambda_1 + \mu_3\mu_1 + \nu_3\nu_1 = 0 && \ \nu_3 = \lambda_1\mu_2 - \mu_1\lambda_2 \\
&(4)\ \lambda_1\mu_1 + \lambda_2\mu_2 + \lambda_3\mu_3 = 0 && (8)\ \begin{vmatrix} \lambda_1 & \mu_1 & \nu_1 \\ \lambda_2 & \mu_2 & \nu_2 \\ \lambda_3 & \mu_3 & \nu_3 \end{vmatrix} = 1 \\
&\ \mu_1\nu_1 + \mu_2\nu_2 + \mu_3\nu_3 = 0 && \\
&\ \nu_1\lambda_1 + \nu_2\lambda_2 + \nu_3\lambda_3 = 0 &&
\end{aligned}$$

For a combination of displacement and rotation, apply the corresponding equations simultaneously.

Spherical or Polar Coordinates. The relations between the rectangular coordinates x, y, z of a point P and its spherical coordinates r, θ, ϕ (Fig. 2), are

$$x = r \sin \phi \sin \theta, \quad y = r \sin \phi \cos \theta, \quad z = r \cos \phi$$

$$r^2 = x^2 + y^2 + z^2, \quad \theta = \tan^{-1} \frac{x}{y}, \quad \phi = \tan^{-1} \frac{\sqrt{x^2 + y^2}}{z} \tag{22}$$

35. QUADRIC SURFACES

The General Form of the Equation of a Surface of the Second Degree is

$$\begin{aligned} F(x, y, z) \equiv a_{11} x^2 + 2a_{12} xy + 2a_{13} xz + a_{22} y^2 + 2a_{23} yz \\ + a_{33} z^2 + 2a_{14} x + 2a_{24} y + 2a_{34} z + a_{44} = 0 \end{aligned} \tag{23}$$

where the a_{ik} are constants, and $a_{ik} = a_{ki}$, i.e., $a_{12} = a_{21}$, etc.

$$\text{Let } D = \begin{vmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ a_{41} & a_{42} & a_{43} & a_{44} \end{vmatrix}, \quad d = \begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix}$$

Let $I \equiv a_{11} + a_{22} + a_{33}$ and $J \equiv a_{22} a_{33} + a_{33} a_{11} + a_{11} a_{22} - a_{23}^2 - a_{13}^2 - a_{12}^2$. I and J are invariant under coordinate transformation. The following is a classification of the quadratic surfaces, so far as they are real and do not degenerate into curves in one plane:

Ellipsoid, for $D < 0$, $d > 0$, $J > 0$.
Hyperboloid of two sheets, for $D < 0$, Id and J not both > 0.
Hyperboloid of one sheet, for $D > 0$, Id and J not both > 0.
Cone, for $D = 0$, $d \neq 0$, Id and J not both > 0.
Elliptic paraboloid, for $D < 0$, $d = 0$, $J > 0$.
Hyperbolic paraboloid, for $D > 0$, $d = 0$, $J < 0$.
Cylinder, for $D = 0$, $d = 0$.

Ellipsoid and Hyperboloids. Consider the center of the quadric as the origin and the principal axes of the quadric as the orthogonal coordinate axes. Then

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1 \text{ is an } \textit{ellipsoid} \text{ (Fig. 4)} \tag{24}$$

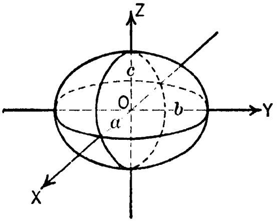

FIG. 4

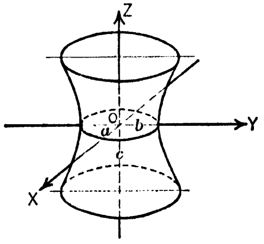

FIG. 5

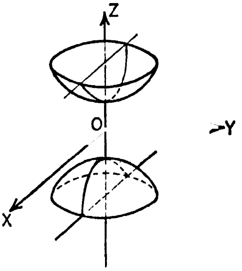

FIG. 6

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1 \text{ is an } \textit{hyperboloid of one sheet} \text{ (Fig. 5)} \tag{25}$$

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = -1 \text{ is an } \textit{hyperboloid of two sheets} \text{ (Fig. 6)} \tag{26}$$

where a, b, c are the semi-axes.

The length of the semi-axes is found from

$$a^2 = -\frac{D}{\lambda_1 d}, \quad b^2 = -\frac{D}{\lambda_2 d}, \quad c^2 = -\frac{D}{\lambda_3 d}, \tag{27}$$

where $\lambda_1, \lambda_2, \lambda_3$ are the real roots of the following cubic equation:

$$\begin{vmatrix} a_{11} - \lambda & a_{12} & a_{13} \\ a_{12} & a_{22} - \lambda & a_{23} \\ a_{13} & a_{23} & a_{33} - \lambda \end{vmatrix} = 0 \tag{28}$$

Cone. The equation

$$ax^2 + by^2 + cz^2 + 2hxy + 2gxz + 2fyz = 0 \tag{29}$$

represents a cone with vertex at the origin. If the cross-section of the cone is an ellipse with axes $2a$ and $2b$, whose plane is parallel to OZ and at a distance c from the origin, then the equation of the cone with vertex at the origin is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 0 \tag{30}$$

If $a = b$, the cross-section is circular, and the cone is a cone of revolution.

Sphere. An equation of the form

$$x^2 + y^2 + z^2 + ax + by + cz + d = 0 \tag{31}$$

represents a sphere with radius

$$r = {}^1/_2 \sqrt{a^2 + b^2 + c^2 - 4d} \tag{32}$$

and center

$$x_0 = - {}^1/_2\, a,\ y_0 = - {}^1/_2\, b,\ z_0 = - {}^1/_2\, c \tag{33}$$

If (x_0, y_0, z_0) are the coordinates of the center and r is the radius, then the equation of the sphere is

$$(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2 = r^2 \tag{34}$$

If $x_0 = 0$, $y_0 = 0$, $z_0 = 0$, then the equation is

$$x^2 + y^2 + z^2 = r^2 \tag{35}$$

Paraboloids. The equation

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 2cz \tag{36}$$

represents an *elliptic paraboloid* (Fig. 7).

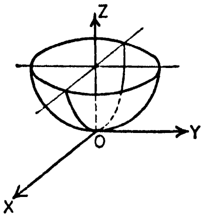

FIG. 7

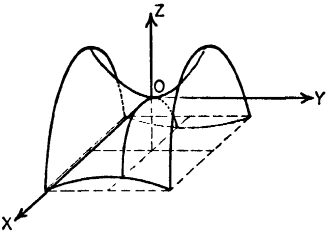

FIG. 8

If $a = b$, the equation is of the form

$$x^2 + y^2 = 2cz, \text{ a paraboloid of revolution.} \tag{37}$$

The equation

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 2cz \text{ represents an hyperbolic paraboloid (Fig. 8).} \tag{38}$$

Cylinder. The equation of a cylinder perpendicular to a coordinate plane XOY, YOZ, or XOZ is the same as the equation of a section of the cylinder in the corresponding coordinate plane. Thus

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \tag{39}$$

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1 \tag{40}$$

$$y^2 = 4ax \tag{41}$$

are *elliptic*, *hyperbolic*, and *parabolic* cylinders respectively with elements or generators parallel to OZ.

Tangent Plane. The equation of the tangent plane to any quadric

$$F(x, y, z) \equiv a_{11}x^2 + 2a_{12}xy + 2a_{13}xz + a_{22}y^2 + 2a_{23}yz + a_{33}z^2 + 2a_{14}x + 2a_{24}y + 2a_{34}z + a_{44} = 0 \tag{42}$$

at the point (x_1, y_1, z_1) is

$$\left(\frac{\partial F}{\partial x}\right)_{x=x_1,\, y=y_1,\, z=z_1}(x-x_1) + \left(\frac{\partial F}{\partial y}\right)_{x=x_1,\, y=y_1,\, z=z_1}(y-y_1) + \left(\frac{\partial F}{\partial z}\right)_{x=x_1,\, y=y_1,\, z=z_1}(z-z_1) = 0 \tag{43}$$

Example. Find the tangent plane to the hyperboloid of one sheet at point (x_1, y_1, z_1).

Given $\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1$

Then $$\left(\frac{\partial F}{\partial x}\right)_{x=x_1,\, y=y_1,\, z=z_1} (x-x_1) + \left(\frac{\partial F}{\partial y}\right)_{x=x_1,\, y=y_1,\, z=z_1} (y-y_1) + \left(\frac{\partial F}{\partial z}\right)_{x=x_1,\, y=y_1,\, z=z_1} (z-z_1)$$
$$= \frac{2x_1(x-x_1)}{a^2} + \frac{2y_1(y-y_1)}{b^2} - \frac{2z_1(z-z_1)}{c^2} = 0.$$

$\frac{xx_1}{a^2} + \frac{yy_1}{b^2} - \frac{zz_1}{c^2} - \frac{x_1^2}{a^2} - \frac{y_1^2}{b^2} + \frac{z_1^2}{c^2} = \frac{xx_1}{a^2} + \frac{yy_1}{b^2} - \frac{zz_1}{c^2} - 1 = 0$ is the tangent plane.

The Normal. The line through a point P_1 on a surface and perpendicular to the tangent plane at P_1 is called the *normal* to the surface at P_1.

The equations of the normal to the surface $F(x, y, z) = 0$ at the point (x_1, y_1, z_1) are

$$\frac{x - x_1}{\left(\frac{\partial F}{\partial x}\right)_{x=x_1,\, y=y_1,\, z=z_1}} = \frac{y - y_1}{\left(\frac{\partial F}{\partial y}\right)_{x=x_1,\, y=y_1,\, z=z_1}} = \frac{z - z_1}{\left(\frac{\partial F}{\partial z}\right)_{x=x_1,\, y=y_1,\, z=z_1}} \tag{44}$$

DIFFERENTIAL CALCULUS

By M. J. Fish

36. FUNCTIONS AND DERIVATIVES

Definition of a Function. A variable y is said to be a function of a variable x if the value of y is determined when the value of x is given. In this definition, x is called the independent variable and y the dependent variable. The symbols $F(x)$, $f(x)$, $\phi(x)$, etc., are used to represent various functions of x, while the symbol $f(a)$ represents the value of $f(x)$ when $x = a$.

Limit, Derivative, Differential, Continuity. The *constant a* is said to be the *limit of a variable x*, if, as the variable changes its value, the numerical difference between the variable and constant becomes and remains less than any small positive constant which may be assigned. The symbol $x \to a$ or $\lim x = a$ is used for this definition. An example of a variable becoming equal to its limit is a swinging pendulum finally coming to rest. An illustration of a variable never reaching its limit is a polygon of n sides inscribed in a circle. No matter how large n is taken, the circumference or area of the polygon never equals that of the circle.

x becomes *infinitely large*, $x \to \infty$, means that the value of x becomes *larger* than any assigned *positive* number. $x \to -\infty$ means that the value of x becomes *smaller* than any assigned *negative* number.

Usually a change in x causes a change in y. A change in x is called an *increment* of x and is denoted by Δx. Similarly a change in y is denoted by Δy. If

$$\lim_{\Delta x \to 0} \frac{f(x + \Delta x) - f(x)}{\Delta x}$$

has a *definite* value, it is called the *derivative* of y with respect to x and is denoted by $\frac{dy}{dx}$ or $f'(x)$.

The geometric interpretation of $f'(x)$ is

$$f'(x) = \frac{dy}{dx} = \tan \theta \tag{1}$$

or $f'(x)$ is equal to the slope of the tangent to the curve $y = f(x)$ at the point of contact $P(x, y)$ (Fig. 1).

$$\lim_{PR \to 0} \frac{RQ}{PR} = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \frac{f(x + \Delta x) - f(x)}{\Delta x} = \frac{dy}{dx} = f'(x) = \tan \theta \tag{2}$$

The differentials of x and y, respectively, are

$$dx = \Delta x$$
$$dy = f'(x)dx$$

Continuity of a Function in an Interval. A function is called *continuous* at $x = b$ if it has a definite value at b and approaches that value as a limit whenever x approaches b as a limit. The notion of continuity at a point suggests that the graph of the function is a smooth curve in the neighborhood of the point. The analytic conditions that $f(x)$ be continuous at b are that $f(b)$ have a definite value and that

$$|f(x) - f(b)| < \epsilon \text{ for } |x - b| < \delta(\epsilon) \tag{3}$$

where ϵ is any positive number which can be chosen as small as desired, while $\delta(\epsilon)$ depends on ϵ. The bars outside of $|f(x) - f(b)|$ show that the *absolute value* or value without the algebraic sign is to be taken; thus $|2 - 5| = |5 - 2| = 3$. A function which is continuous at each point of an interval is said to be continuous in that interval. An example of a continuous function is $f(x) = x^2$. The function $\phi(x) = \dfrac{1}{x - a}$ is continuous for all values of x other than $x = a$, at which point it becomes infinite. Every differentiable function is continuous, although the reverse is not always true.

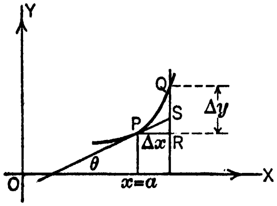

Fig. 1

If, in the above definition of continuity, the number δ can be chosen the same for all points in the interval, the function is said to be *uniformly continuous* in that interval.

Derivatives of Higher Order. The *derivative* of the *first derivative* of y with respect to x is called the *second derivative of y with respect to x* and is denoted by

$$\frac{d}{dx}\left(\frac{dy}{dx}\right) = \frac{d^2 y}{dx^2} \quad \text{or} \quad f''(x) \tag{4}$$

$$\frac{d^3 y}{dx^3} \quad \text{or} \quad f'''(x) \tag{5}$$

is the third derivative of y with respect to x. If $y = f(x)$, the second differential of $f(x)$ is

$$d^2 f = f''(x)dx^2 \tag{6}$$

Indeterminate Forms

If a function $f(x)$ for $x = a$ (where a can also be ∞) has no determined value but appears in one of the meaningless forms

$$\frac{0}{0}, \frac{\infty}{\infty}, 0\cdot\infty, \infty - \infty, 0^0, \infty^0, 0^\infty, 1^\infty$$

then it may happen that the $\lim\limits_{x \to a} f(x)$ has a definite value. For the determination of this limiting value, if it exists, the following rules can be used:

$\mathbf{\frac{0}{0}}$. If $f(x) = \dfrac{\phi(x)}{\psi(x)}$, $\phi(a) = 0$, and $\psi(a) = 0$, then

$$\lim_{x \to a} f(x) = \lim_{x \to a} \frac{\phi'(x)}{\psi'(x)} \qquad \text{(L'Hospital's rule)} \tag{7}$$

If, however, $\phi'(a) = 0$ and $\psi'(a) = 0$, the rule is applied again, with the result

$$\lim_{x \to a} \frac{\phi(x)}{\psi(x)} = \lim_{\xi \to a} \frac{\phi'(\xi)}{\psi'(\xi)} = \frac{\phi''(a)}{\psi''(a)} \tag{8}$$

unless $\phi''(a) = 0$ and $\psi''(a) = 0$. In this case, the rule is applied again.

Example. Find the value of $\dfrac{\sin x}{x}$ for $x = 0$.

$$\lim_{x \to 0} \frac{\sin x}{x} = \lim_{x \to 0} \frac{\cos x}{1} = 1.$$

$\mathbf{\frac{\infty}{\infty}}$. If $f(x) = \dfrac{\phi(x)}{\psi(x)}$, $\phi(a) = \infty$, and $\psi(a) = \infty$, then

$$\lim_{x \to a} \frac{\phi(x)}{\psi(x)} = \lim_{x \to a} \frac{\phi'(x)}{\psi'(x)} \tag{9}$$

as before.

$\mathbf{0 \cdot \infty}$. If $f(x) = \phi(x) \cdot \psi(x)$, $\phi(a) = 0$, and $\psi(a) = \infty$, then place $\dfrac{1}{\psi(x)} = \omega(x)$ and obtain the previous case $\dfrac{0}{0}$.

$\mathbf{\infty - \infty}$. If $f(x) = \phi(x) - \psi(x)$, $\phi(a) = \infty$, and $\psi(a) = \infty$, then place $\phi(x) = \dfrac{1}{u(x)}$, $\psi(x) = \dfrac{1}{v(x)}$ and obtain

$$f(x) = \frac{v(x) - u(x)}{u(x)v(x)} \tag{10}$$

which takes the form $\dfrac{0}{0}$.

0°, ∞°, 0^∞, 1^∞. An expression of the type $[\psi(x)]^{\phi(x)}$ may, for $x = a$, give rise to the forms 0°, ∞°, 0^∞, 1^∞.

Such an expression may be reduced to a type $\frac{0}{0}$ or $\frac{\infty}{\infty}$ by the use of logarithms. Thus,

$$\left.\begin{aligned} u &= [\psi(x)]^{\phi(x)} \\ \log_e u &= \phi(x)\cdot\log_e \psi(x) \end{aligned}\right\} \qquad (11)$$

If $\lim\limits_{x\to a} \phi(x)\cdot\log_e \psi(x)$ can be found by the previous methods, the limit approached by u can be found.

Example. $u = (1 - x)^{1/x}$ for $x = 0$

$$\log_e u = \frac{\log_e (1 - x)}{x}$$

$$\lim_{x\to 0} \frac{\log_e (1 - x)}{x} = -1$$

Therefore $\lim\limits_{x\to 0} \log_e u = -1$ and $\lim\limits_{x\to 0} u = e^{-1}$

37. DIFFERENTIATION FORMULAS

Table I. Differentiation Formulas

Let $u, v, w, \ldots$ be functions of x; a and n be constants; and e be the base of the natural or Napierian logarithms. Then $e = 2.7183^-$.

$$\frac{d}{dx} a = 0$$

$$\frac{d}{dx}(u + v + w + \ldots) = \frac{du}{dx} + \frac{dv}{dx} + \frac{dw}{dx} + \ldots$$

$$\frac{d}{dx} au = a\frac{du}{dx}$$

$$\frac{d}{dx} uv = u\frac{dv}{dx} + v\frac{du}{dx}$$

$$\frac{d}{dx}(uvw\ldots) = \left(\frac{1}{u}\frac{du}{dx} + \frac{1}{v}\frac{dv}{dx} + \frac{1}{w}\frac{dw}{dx} + \ldots\right)(uvw\ldots)$$

$$\frac{d}{dx}\left(\frac{u}{v}\right) = \frac{v\dfrac{du}{dx} - u\dfrac{dv}{dx}}{v^2}$$

$$\frac{d}{dx} u^n = nu^{n-1}\frac{du}{dx}$$

$$\frac{d}{dx} \log_e u = \frac{1}{u}\frac{du}{dx}$$

$$\frac{d}{dx} \log_{10} u = \frac{1}{u}\frac{du}{dx}\log_{10} e = (0.4343)\frac{1}{u}\frac{du}{dx}$$

$$\frac{d}{dx} e^u = e^u\frac{du}{dx}$$

$$\frac{d}{dx} u^v = vu^{v-1}\frac{du}{dx} + u^v\frac{dv}{dx}\log_e u$$

$$\frac{d}{dx} f(u) = \frac{df(u)}{du}\cdot\frac{du}{dx}$$

$$\frac{d^2 f(u)}{dx^2} = \frac{df(u)}{du}\cdot\frac{d^2 u}{dx^2} + \frac{d^2 f(u)}{du^2}\left(\frac{du}{dx}\right)^2$$

$$\frac{d}{dx}\sin u = \cos u\frac{du}{dx}$$

$$\frac{d}{dx}\cos u = -\sin u\frac{du}{dx}$$

$$\frac{d}{dx}\tan u = \sec^2 u\frac{du}{dx}$$

$$\frac{d}{dx}\cot u = -\csc^2 u\frac{du}{dx}$$

$$\frac{d}{dx}\sec u = \sec u\tan u\frac{du}{dx}$$

$$\frac{d}{dx}\csc u = -\csc u\cot u\frac{du}{dx}$$

$$\frac{d}{dx}\sin^{-1} u = \frac{1}{\sqrt{1 - u^2}}\frac{du}{dx}\quad\left(-\frac{\pi}{2} \leqq \sin^{-1} u \leqq \frac{\pi}{2}\right)$$

$$\frac{d}{dx}\cos^{-1} u = -\frac{1}{\sqrt{1 - u^2}}\frac{du}{dx}\quad(0 \leqq \cos^{-1} u \leqq \pi)$$

$$\frac{d}{dx}\tan^{-1} u = \frac{1}{1 + u^2}\frac{du}{dx}$$

$$\frac{d}{dx}\cot^{-1} u = -\frac{1}{1 + u^2}\frac{du}{dx}$$

$$\frac{d}{dx}\sec^{-1} u = \frac{1}{u\sqrt{u^2 - 1}}\frac{du}{dx}\,{}^*$$

$$\frac{d}{dx}\csc^{-1} u = -\frac{1}{u\sqrt{u^2 - 1}}\frac{du}{dx}\,{}^*$$

$$\frac{d}{dx}\sinh u = \cosh u\frac{du}{dx}$$

$$\frac{d}{dx}\cosh u = \sinh u\frac{du}{dx}$$

$$\frac{d}{dx}\tanh u = \operatorname{sech}^2 u\frac{du}{dx}$$

$$\frac{d}{dx}\coth u = -\operatorname{csch}^2 u\frac{du}{dx}$$

$$\frac{d}{dx}\operatorname{sech} u = -\operatorname{sech} u\tanh u\frac{du}{dx}$$

$$\frac{d}{dx}\operatorname{csch} u = -\operatorname{csch} u\coth u\frac{du}{dx}$$

$$\frac{d}{dx}\sinh^{-1} u = \frac{1}{\sqrt{u^2 + 1}}\frac{du}{dx}$$

$$\frac{d}{dx}\cosh^{-1} u = \frac{1}{\sqrt{u^2 - 1}}\frac{du}{dx}$$

$$\frac{d}{dx}\tanh^{-1} u = \frac{1}{1 - u^2}\frac{du}{dx}$$

$$\frac{d}{dx}\coth^{-1} u = \frac{1}{1 - u^2}\frac{du}{dx}$$

$$\frac{d}{dx}\operatorname{sech}^{-1} u = -\frac{1}{u\sqrt{1 - u^2}}\frac{du}{dx}$$

$$\frac{d}{dx}\operatorname{csch}^{-1} u = -\frac{1}{u\sqrt{u^2 + 1}}\frac{du}{dx}$$

---

* For angles in the first and third quadrants. Use the opposite sign in the second and fourth quadrants.

38. PARTIAL DERIVATIVES

Functions of Two Variables and Partial Derivatives. A quantity $f(x, y)$ is a function of two variables, if the value of f is determined when the values of x and y are given. If x is considered as the only variable while y is taken as constant, then the derivative of $f(x, y)$ with respect to x is called the *partial derivative* of f with respect to x and is denoted by

$$\frac{\partial f}{\partial x} = f_x = \lim_{\Delta x \to 0} \frac{f(x + \Delta x, y) - f(x, y)}{\Delta x} \tag{12}$$

Likewise, the partial derivative of f with respect to y is obtained by considering x to be constant while y varies:

$$\frac{\partial f}{\partial y} = f_y = \lim_{\Delta y \to 0} \frac{f(x, y + \Delta y) - f(x, y)}{\Delta y} \tag{13}$$

If $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ are again differentiable, the partial derivatives of the second order may be found.

$$\begin{aligned} &\frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x}\right) = \frac{\partial^2 f}{\partial x^2} = f_{xx} \qquad &\frac{\partial}{\partial y}\left(\frac{\partial f}{\partial y}\right) = \frac{\partial^2 f}{\partial y^2} = f_{yy} \\ &\frac{\partial}{\partial x}\left(\frac{\partial f}{\partial y}\right) = \frac{\partial^2 f}{\partial x \partial y} = f_{yx} \qquad &\frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x}\right) = \frac{\partial^2 f}{\partial y \partial x} = f_{xy} \end{aligned} \tag{14}$$

But under the conditions that $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ are continuous functions,

$$\frac{\partial^2 f}{\partial y \partial x} = \frac{\partial^2 f}{\partial x \partial y} \tag{15}$$

which means that the order of differentiation for the second partial derivatives is interchangeable.

Similarly, the third partial derivatives of $f(x,y)$ are four in number:

$$\begin{aligned} &\frac{\partial}{\partial x}\left(\frac{\partial^2 f}{\partial x^2}\right) = \frac{\partial^3 f}{\partial x^3} \qquad &\frac{\partial}{\partial x}\left(\frac{\partial^2 f}{\partial y^2}\right) = \frac{\partial}{\partial y}\left(\frac{\partial^2 f}{\partial x \partial y}\right) = \frac{\partial^2}{\partial y^2}\left(\frac{\partial f}{\partial x}\right) = \frac{\partial^3 f}{\partial x \partial y^2} \\ &\frac{\partial}{\partial y}\left(\frac{\partial^2 f}{\partial y^2}\right) = \frac{\partial^3 f}{\partial y^3} \qquad &\frac{\partial}{\partial y}\left(\frac{\partial^2 f}{\partial x^2}\right) = \frac{\partial}{\partial x}\left(\frac{\partial^2 f}{\partial x \partial y}\right) = \frac{\partial^2}{\partial x^2}\left(\frac{\partial f}{\partial y}\right) = \frac{\partial^3 f}{\partial x^2 \partial y} \end{aligned} \tag{16}$$

The formulas above may be generalized to the case where f is a function of more than two variables; $f(x, y, z, \ldots)$ is determined if values for $x, y, z, \ldots$ are given. If the increments $\Delta x, \Delta y, \Delta z, \ldots$ are assigned to $x, y, z, \ldots$ in $f(x, y, z, \ldots)$, the following is obtained:

The total increment of f is

$$\Delta f = f(x + \Delta x, y + \Delta y, z + \Delta z, \ldots) - f(x, y, z, \ldots) \tag{17}$$

The total differential of f is

$$df = \frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy + \frac{\partial f}{\partial z} dz + \ldots \tag{18}$$

The second total differential of f is

$$d^2 f = \frac{\partial^2 f}{\partial x^2}(dx)^2 + \frac{\partial^2 f}{\partial y^2}(dy)^2 + \frac{\partial^2 f}{\partial z^2}(dz)^2 + \ldots + 2\frac{\partial^2 f}{\partial x \partial y} dx dy + \ldots \tag{19}$$

In general, $$d^n f = \left(\frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy + \frac{\partial f}{\partial z} dz + \ldots\right)^n \tag{20}$$

where after the development ∂f^n is to be replaced by $\partial^n f$.

Exact Differential. In order for the expression $P(x, y)dx + Q(x, y)\,dy$ to be the *exact* or *complete* differential of a function of two variables, it is necessary and sufficient that

$$\frac{\partial Q}{\partial x} = \frac{\partial P}{\partial y} \quad \text{(integrability condition)} \tag{21}$$

For three variables, $P\,dx + Q\,dy + R\,dz$, the corresponding conditions are

$$\frac{\partial Q}{\partial z} = \frac{\partial R}{\partial y}, \quad \frac{\partial R}{\partial x} = \frac{\partial P}{\partial z}, \quad \frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x} \tag{22}$$

Differentiation of Composite Functions. If $u = f(x, y, z, \ldots w)$, and $x, y, z, \ldots w$ are functions of a single variable t, then

$$\frac{du}{dt} = \frac{\partial u}{\partial x}\frac{dx}{dt} + \frac{\partial u}{\partial y}\frac{dy}{dt} + \ldots + \frac{\partial u}{\partial w}\frac{dw}{dt} \tag{23}$$

which is the total derivative of u with respect to t.

Example. Given: $u = x^2 + y^2 + 3xy,\ x = t^2,\ y = \frac{1}{t}$.

Then $\frac{dx}{dt} = 2t,\ \frac{dy}{dt} = -\frac{1}{t^2}$

and $\frac{du}{dt} = \left(2t^2 + \frac{3}{t}\right)2t - \left(\frac{2}{t} + 3t^2\right)\frac{1}{t^2}$

The equation reduces to $\frac{du}{dt} = 4t^3 + 3 - \frac{2}{t^3}$

which expresses the rate of change of u with respect to t as a function of t.

Implicit Functions. The equation $F(x, y) = 0$ defines y as an *implicit* function of x, and x as an implicit function of y. If the equation is solved for y in terms of x, $y = f(x)$, then y is called an *explicit* function of x. An example of an elementary case of $F(x, y) = 0$ which can be solved for $y = f(x)$ is

$$x^2 + y^2 - r^2 = 0 \text{ which gives } y = \sqrt{r^2 - x^2} \tag{24}$$

To find $\frac{dy}{dx}$, either differentiate $y = f(x)$ or use

$$\frac{dy}{dx} = -\frac{\frac{\partial F}{\partial x}}{\frac{\partial F}{\partial y}} \qquad \left(\frac{\partial F}{\partial y} \neq 0\right) \tag{25}$$

$$\frac{d^2 y}{dx^2} = -\frac{\frac{\partial^2 F}{\partial x^2}\left(\frac{\partial F}{\partial y}\right)^2 - 2\frac{\partial^2 F}{\partial x \partial y}\frac{\partial F}{\partial x}\frac{\partial F}{\partial y} + \frac{\partial^2 F}{\partial y^2}\left(\frac{\partial F}{\partial x}\right)^2}{\left(\frac{\partial F}{\partial y}\right)^3} \qquad \left(\frac{\partial F}{\partial y} \neq 0\right) \tag{26}$$

39. SERIES EXPANSION OF FUNCTIONS

Mean Value Theorem. If $f(x)$ is *single valued, continuous* in the interval $a \leqq x \leqq b$, and has a derivative for all values of x between a and b, then

$$f(b) - f(a) = (b - a)f'(\xi) \tag{27}$$

where ξ is a value of x between a and b; if

$$\xi = x + \theta h,\ 0 < \theta < 1 \tag{28}$$

another form is

$$f(x + h) = f(x) + h f'(\xi) \tag{29}$$

Taylor's Formula. If $f(x)$ and all its derivatives are continuous in the neighborhood of the point $x = a$, then $f(x)$ can be developed into a power series arranged according to ascending powers of $x - a$. The series is:

$$f(x) = f(a) + \frac{f'(a)}{1!}(x - a) + \frac{f''(a)}{2!}(x - a)^2 + \ldots + \frac{f^{(n-1)}(a)}{(n - 1)!}(x - a)^{n-1} + R_n \tag{30}$$

where $n! = n(n - 1)(n - 2)\ldots 2 \cdot 1$, and is called factorial n, and

$$R_n = \frac{f^n(\xi)}{n!}(x - a)^n \tag{31}$$

is the *remainder* after n terms of the series and

$$\xi = a + \theta(x - a),\ 0 < \theta < 1 \tag{32}$$

Another form:

$$f(x + h) = f(x) + \frac{h}{1!}f'(x) + \frac{h^2}{2!}f''(x) + \ldots + \frac{h^{n-1}}{(n - 1)!}f^{(n-1)}(x) + R_n \tag{33}$$

where $R_n = \frac{h^n}{n!}f^n(\xi),\ \xi = x + \theta h,\ 0 < \theta < 1$ (34)

Maclaurin's Form of Taylor's Formula (for $a = 0$).

$$f(x) = f(0) + \frac{f'(0)}{1!}x + \frac{f''(0)}{2!}x^2 + \ldots + \frac{f^{(n-1)}(0)}{(n - 1)!}x^{n-1} + R_n \tag{35}$$

where $R_n = \frac{f^n(\xi)}{n!}x^n,\ \xi = \theta x,\ 0 < \theta < 1$ (36)

Care must be exercised in using these formulas that the *series converges*, that is, $\lim_{n \to \infty} R_n = 0$. If Taylor's series converges rapidly, the sum of the first few terms gives a good approximation to $f(x)$ for values of x near $x = a$. If Maclaurin's series converges rapidly, the sum of the first few terms gives a good approximation to $f(x)$ for values of x near $x = 0$. That not all functions can be expanded into Maclaurin's series is shown by the examples; $f(x) = \frac{1}{x}; \frac{1}{x^2}; \sqrt{x}, \frac{1}{\sqrt{x}}; \log_e x; \cot x;$ etc.

Example. Expand e^{nx} into a series of ascending powers of x.

$$\begin{aligned} f(x) &= e^{nx}, & f(0) &= 1 \\ f'(x) &= ne^{nx}, & f'(0) &= n \\ f''(x) &= n^2e^{nx}, & f''(0) &= n^2 \\ f'''(x) &= n^3e^{nx}, & f'''(0) &= n^3 \\ f^{\mathrm{IV}}(x) &= n^4e^{nx}, & f^{\mathrm{IV}}(0) &= n^4 \end{aligned}$$

$$e^{nx} = 1 + \frac{n}{1!}x + \frac{n^2}{2!}x^2 + \frac{n^3}{3!}x^3 + \dots$$

If x and n are less than unity, this series converges rapidly.

Taylor's Formula for Two Variables.

$$f(x + h, y + k) = f(x, y) + \frac{1}{1!}\left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right)^{(1)} f(x, y) + \frac{1}{2!}\left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right)^{(2)} f(x, y) + \dots$$

$$\dots + \frac{1}{(n-1)!}\left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right)^{(n-1)} f(x, y) + R_n \tag{37}$$

where

$$R_n = \frac{1}{n!}\left(h\frac{\partial}{\partial x} + k\frac{\partial}{\partial y}\right)^{(n)} f(x + \theta h, y + \theta k),\ 0 < \theta < 1 \tag{38}$$

Infinite Series. The expression

$$a_0 + a_1 x + a_2 x^2 + a_3 x^3 + \dots + a_n x^n + \dots \tag{39}$$

is a *power series*. If the number of terms is finite, the power series is a polynomial; if infinite, the power series is an *infinite* series. The series above is said to *converge* for a given value $x = b$, if the sum of the first n terms approaches a limit L as n is indefinitely increased; $s_n \to L$ as $n \to \infty$. The limit L is called the *value* of the series. The geometric series is an example of a power series:

$$1 + x + x^2 + x^3 + \dots x^n + \dots \tag{40}$$

From algebra, the sum of the first n terms of this series is

$$\frac{1 - x^n}{1 - x} = \frac{1}{1 - x} - \frac{x^n}{1 - x} \tag{41}$$

If $|x| < 1$, the last fraction above approaches zero as $n \to \infty$, and s_n, the sum of the first n terms, approaches the limit $\frac{1}{1 - x}$. Hence, the geometric series converges for any value of x in the interval $-1 < x < 1$.

A series which does not converge is called *divergent*. An example is the harmonic series

$$1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \dots + \frac{1}{n} + \dots \tag{42}$$

Absolute Convergence. If in the series (39) each term is replaced by its absolute value and if the new series

$$|a_0| + |a_1x| + |a_2x^2| + |a_3x^2| + \dots + |a_nx^n| + \dots \tag{43}$$

converges for a given value of x, then series (39) is called *absolutely convergent* for that value of x. If series (43) is convergent, then so is series (39). The determination of the convergence of series (43) is then the determination of the convergence of a series of positive terms. Series, which though convergent are not so absolutely, are called *conditionally convergent.*

Tests for Convergence

Comparison Test. If no term of a series of positive numbers is greater than the corresponding term of a known convergent series, then the first series converges. If no term of a given series is less than the corresponding term of a known divergent series of positive numbers, then the first series diverges.

Ratio Test. If, in a series of positive numbers, the ratio of the $(n + 1)$st term to the nth term approaches a limit L as $n \to \infty$, and if $L < 1$, the series converges; if $D > 1$, the series diverges; if $L = 1$, the test fails.

Raabe's Test. A series of positive functions of x,

$$u_0(x) + u_1(x) + u_2(x) + \ldots + u_n(x) + \ldots \tag{44}$$

is convergent, if there is a sufficiently large N such that for all $n > N$, k being a constant > 1

$$\frac{u_n}{u_{n+1}} \geqq 1 + \frac{k}{n} \tag{45}$$

On the contrary, the series is divergent if

$$\frac{u_n}{u_{n+1}} \leqq 1 + \frac{1}{n} \tag{46}$$

In particular, the series is convergent or divergent according to whether the expression $n\left(\frac{u_n}{u_{n+1}} - 1\right)$ has a limit > 1 or < 1, respectively.

One of the above tests may indicate the convergence or divergence of the series in cases where the other tests give no information.

Conditional Convergence. If, in a series of alternately positive and negative terms, each term is less in absolute value than the preceding term, and the absolute value of the nth term approaches zero as a limit as $n \rightarrow \infty$, the series converges.

For example, the series:

$$a_0 - a_1 + a_2 - a_3 + \ldots + (-1)^n a_n + \ldots \tag{47}$$

in which the a's are positive numbers with $a_{n+1} < a_n$ and $\lim_{n \rightarrow \infty} a_n = 0$, converges.

Region of Convergence of Power Series. Given the power series

$$a_0 + a_1 x + a_2 x^2 + \ldots + a_n x^n + \ldots \tag{48}$$

If the ratio $\frac{|a_{n+1}|}{|a_n|}$ approaches a limit L as $n \rightarrow \infty$, then the ratio $\frac{|a_{n+1}|}{|a_n|} |x|$ approaches a limit $L\,|x|$ which is less than 1 if $|x| < \frac{1}{L}$ and greater than 1 if $|x| > \frac{1}{L}$. The region of convergence is then determined as the interval $-\frac{1}{L} < x < \frac{1}{L}$.

Example. Find the region of convergence of the power series

$$2 + 4x + 6x^2 + \ldots + 2nx^{n-1} + 2(n+1)x^n + \ldots$$

$$\frac{|a_{n+1}|}{|a_n|}|x| = \frac{|2(n+1)|}{|2n|}|x| = \frac{n+1}{n}|x|$$

As $n \rightarrow \infty$, this latter approaches the limit Lx which, in this case, equals x. The region of convergence is $-1 < x < 1$.

Uniform Convergence. The relation of uniform convergence to that of convergence is somewhat like that of uniform continuity to that of continuity of a function. Consider a series of functions of a variable x

$$f(x) = u_0(x) + u_1(x) + u_2(x) + \ldots + u_n(x) + R_n(x) \tag{49}$$

where $R_n(x)$ is the remainder after n terms. Given ϵ, a positive quantity which can be made as small as desired. If $|R_n(x)| < \epsilon$ for all the indices n larger than a given number N, which is independent of the value of x in the interval $a < x < b$, then the series is uniformly convergent in that interval. Note that once N is determined it is valid for all values of x in that interval. If the power series

$$a_0 + a_1 x + a_2 x^2 + \ldots + a_n x^n + \ldots \tag{50}$$

has the interval of convergence $-R < x < R$, then the series (50) is uniformly convergent in any interval within this interval. If series (49) is a uniformly convergent series of continuous functions, then $f(x)$, the limit of the sum of the $u_n(x)$, is a continuous function. It is this property which allows such a series to be differentiated or integrated term by term.

Weierstrass' Test for the Uniform Convergence of a Series in an Interval. If series (49) above is given such that, for all values of x in an interval, the absolute values of the terms of the series are respectively less than the corresponding terms in a convergent series of positive constant terms $T = M_1 + M_2 + M_3 + \ldots + M_n + \ldots$, then the series (49) is uniformly convergent in this interval.

Example. The series $\cos x + \frac{1}{2^2}\cos^2 x + \frac{1}{3^2}\cos^3 x + \ldots$ is uniformly convergent for all values

of x because the absolute values of its terms are not greater than the corresponding terms of the convergent series

$$1 + \frac{1}{2^2} + \frac{1}{3^2} + \dots$$

Operations with Series. A uniformly convergent series of continuous functions may be differentiated term by term. Given the series (49) above uniformly convergent in $a < x < b$ where the $u_n(x)$ are continuous. Then

$$f'(x) = u_0'(x) + u_1'(x) + \dots + u_n'(x) + \dots \tag{51}$$

which converges in the same interval as $f(x)$. If, in turn, $f'(x)$ is uniformly convergent in this same interval

$$f''(x) = u_0''(x) + u_1''(x) + \dots + u_n''(x) + \dots \tag{52}$$

which converges in the same interval. The reasoning above can be repeated. In particular, a power series may be differentiated term by term.

A uniformly convergent series of continuous functions may be integrated term by term. Given

$$f(x) = u_0(x) + u_1(x) + u_2(x) + \dots + u_n(x) + \dots \tag{53}$$

uniformly convergent in $a < x < b$ where the $u_n(x)$ are continuous. Then

$$\int_a^b f(x)dx = \int_a^b u_0(x)dx + \int_a^b u_1(x)dx + \dots + \int_a^b u_n(x)dx + \dots \tag{54}$$

In particular, this is true if $f(x)$ defines a power series.

Two power series may be added, multiplied together, or divided one by the other, and the result is a power series which converges when both of the first do and represents the sum, product, or quotient, respectively, of the two series.

Trigonometric or Fourier Series

If the infinite series

$$\frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx) = \frac{1}{2} a_0 + a_1 \cos x + a_2 \cos 2x$$
$$+ a_3 \cos 3x + \dots + b_1 \sin x + b_2 \sin 2x + b_3 \sin 3x + \dots \tag{55}$$

converges over an interval of length 2π in x, say $0 \leqq x < 2\pi$ or $-\pi < x \leqq \pi$, the series converges for all values of x and defines a periodic function $f(x + 2\pi) = f(x)$ of period 2π. To determine the coefficients, use the formulas

$$a_0 = \frac{1}{\pi}\int_0^{2\pi} f(x)dx,\ a_k = \frac{1}{\pi}\int_0^{2\pi} f(x) \cos k\,x\,dx,\ b_k = \frac{1}{\pi}\int_0^{2\pi} f(x) \sin k\,x\,dx \tag{56}$$

Conversely, if $f(x)$ is a function, single-valued and finite in an interval of length 2π, and continuous except for a finite number of discontinuities (jumps) in the interval, the numbers a_0, a_k, b_k may be computed as above and the series constructed. If the series converges to the value of $f(x)$, there has been found an expansion of $f(x)$ over the interval from 0 to 2π in a Fourier series. For questions of convergence and term-by-term differentiation and integration consult a book on Fourier series.

Example. Develop e^x in the interval 0 to 2π.

$$a_0 = \frac{1}{\pi}\int_0^{2\pi} e^x\,dx = \frac{1}{\pi}(e^{2\pi} - 1),\ a_k = \frac{1}{\pi}\int_0^{2\pi} e^x \cos k\,x\,dx = \frac{e^{2\pi} - 1}{\pi(k^2 + 1)},\ b_k = -\frac{k(e^{2\pi} - 1)}{\pi(k^2 + 1)}$$

Hence

$$e^x = \frac{1}{\pi}(e^{2\pi} - 1)\left[\frac{1}{2} + \frac{1}{1^2 + 1}\cos x + \frac{1}{2^2 + 1}\cos 2\,x + \frac{1}{3^2 + 1}\cos 3x + \dots\right]$$
$$- \frac{1}{\pi}(e^{2\pi} - 1)\left[\frac{1}{1^2 + 1}\sin x + \frac{2}{2^2 + 1}\sin 2x + \frac{3}{3^2 + 1}\sin 3x + \dots\right] \tag{57}$$

The expansion is valid only in the interval from 0 to 2π; outside that interval the series repeats itself owing to the periodic property of sin kx and cos kx. It may be remarked that the expansion does not give the value of the function for 0 or 2π but gives the point midway in the jump. If series (57) were differentiated the coefficients of the cosine terms (after differentiation) would be $1 + \frac{1}{k^2}$ and would not approach 0 when k became infinite, so that the series would evidently oscillate.

The Fourier Series with Sines or Cosines Only. If $f(x) = f(-x)$, it is called an *even* function; if $f(-x) = -f(x)$, it is called an *odd* function. If $f(x)$ is even, so is $f(x) \cos kx$, while $f(x) \sin kx$ is odd. Then

$$a_k = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x) \cos kx\,dx = \frac{2}{\pi}\int_0^{\pi} f(x) \cos kx\,dx \quad \text{(also holds for } k = 0\text{)} \tag{58a}$$

$$b_k = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x) \sin kx\,dx = 0 \tag{58b}$$

Hence an even function may be expanded into a series of cosines in the interval $-\pi < x < \pi$ and the coefficients computed as in (58*a*) and (58*b*).

If $f(x)$ is an odd function, so is $f(x) \cos kx$, while $f(x) \sin kx$ is even. Then

$$a_k = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x) \cos kx \, dx = 0 \qquad (59a)$$

$$b_k = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x) \sin kx \, dx = \frac{2}{\pi}\int_{0}^{\pi} f(x) \sin kx \, dx \qquad (59b)$$

Hence an odd function may be expanded into a series of sines in the interval $-\pi < x < \pi$, and the coefficients computed as in (59*a*) and (59*b*).

It follows that any function $f(x)$ of the type which may be expanded into a Fourier series can be expanded into a series of sines only or a series of cosines only. For a function $\phi(x)$ may be defined equal to $f(x)$ between 0 and π and $\phi(-x) = -f(x)$. Then $\phi(x)$ is an odd function and can be expanded into a sine series. Or, for a cosine series, $\phi(x)$ may be defined as equal to $f(x)$ between 0 and π and $\phi(-x) = f(x)$. Then $\phi(x)$ is an even function and can be expanded into a cosine series.

Example. Expand $f(x) = x$ into a cosine series in the interval $(0, \pi)$.

Here
$$\frac{1}{2}a_0 = \frac{1}{\pi}\int_0^{\pi} x dx = \frac{\pi}{2}$$

$$a_k = \frac{2}{\pi}\int_0^{\pi} x \cos k\,x \, dx = \frac{2}{\pi}\left\{\left[\frac{x \sin kx}{k}\right]_0^{\pi} - \int_0^{\pi} \frac{\sin kx}{k}\,dx\right\}$$

$$= \frac{2}{\pi}\left[\frac{1}{k^2}\cos kx\right]_0^{\pi} = \frac{2}{\pi k^2}(\cos k\pi - 1)$$

Therefore
$$x = \frac{\pi}{2} - \frac{4}{\pi}\left[\cos x + \frac{\cos 3x}{3^2} + \frac{\cos 5x}{5^2} + \dots\right] \quad (0 < x < \pi)$$

If $x = 0$, the sum of the series is zero, if $x = \pi$, the sum of the series is π.

Table II. Functions Expanded into Series

$(\log = \log_e)$

$$(a + x)^n = a^n + na^{n-1}x + \frac{n(n-1)}{2!}a^{n-2}x^2 + \frac{n(n-1)(n-2)}{3!}a^{n-3}x^3 + \dots \qquad (x^2 < a^2)$$

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \dots \qquad (-\infty < x < \infty)$$

$$a^x = 1 + x\log a + \frac{(x\log a)^2}{2!} + \frac{(x\log a)^3}{3!} + \dots \qquad (-\infty < x < \infty)$$

$$e^{-x^2} = 1 - x^2 + \frac{x^4}{2!} - \frac{x^6}{3!} + \frac{x^8}{4!} - \dots \qquad (-\infty < x < \infty)$$

$$e^{\sin x} = 1 + x + \frac{x^2}{2!} - \frac{3x^4}{4!} - \frac{8x^5}{5!} - \frac{3x^6}{6!} + \frac{56x^7}{7!} + \dots \qquad (-\infty < x < \infty)$$

$$e^{\cos x} = e\left(1 - \frac{x^2}{2!} + \frac{4x^4}{4!} - \frac{31x^6}{6!} + \dots\right) \qquad (-\infty < x < \infty)$$

$$e^{\tan x} = 1 + x + \frac{x^2}{2!} + \frac{3x^3}{3!} + \frac{9x^4}{4!} + \frac{37x^5}{5!} + \dots \qquad \left(-\frac{\pi}{2} < x < \frac{\pi}{2}\right)$$

$$\log x = \frac{x-1}{x} + \frac{1}{2}\left(\frac{x-1}{x}\right)^2 + \frac{1}{3}\left(\frac{x-1}{x}\right)^3 + \dots \qquad \left(x > \frac{1}{2}\right)$$

$$\log x = 2\left[\frac{x-1}{x+1} + \frac{1}{3}\left(\frac{x-1}{x+1}\right)^3 + \frac{1}{5}\left(\frac{x-1}{x+1}\right)^5 + \dots\right] \qquad (x > 0)$$

$$\log(1 + x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \dots \qquad (-1 < x < 1)$$

$$\log\left(\frac{1+x}{1-x}\right) = 2\left[x + \frac{x^3}{3} + \frac{x^5}{5} + \frac{x^7}{7} + \dots\right] \qquad (-1 < x < 1)$$

$$\log\left(\frac{x+1}{x-1}\right) = 2\left[\frac{1}{x} + \frac{1}{3}\left(\frac{1}{x}\right)^3 + \frac{1}{5}\left(\frac{1}{x}\right)^5 + \dots\right] \qquad (-1 < x < 1)$$

$$\log \sin x = \log x - \frac{x^2}{6} - \frac{x^4}{180} - \frac{x^6}{2835} - \dots \qquad (-\pi < x < \pi)$$

Table II. Functions Expanded into Series (*Continued*)

$$\log \cos x = -\frac{x^2}{2} - \frac{x^4}{12} - \frac{x^6}{45} - \frac{17x^8}{2520} - \dots \qquad \left(-\frac{\pi}{2} < x < \frac{\pi}{2}\right)$$

$$\log \tan x = \log x + \frac{x^2}{3} + \frac{7x^4}{90} + \frac{62x^6}{2835} + \dots \qquad \left(-\frac{\pi}{2} < x < \frac{\pi}{2}\right)$$

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots \qquad (-\infty < x < \infty)$$

$$\operatorname{csch} x = \frac{1}{x} - \frac{x}{6} + \frac{7x^3}{360} - \frac{31x^5}{15120} + \dots \qquad (-\pi < x < \pi)$$

$$\sinh^{-1} x = x - \frac{x^3}{2\cdot 3} + \frac{3x^5}{2\cdot 4\cdot 5} - \frac{3\cdot 5x^7}{2\cdot 4\cdot 6\cdot 7} + \dots \qquad (-1 < x < 1)$$

$$\sinh^{-1} x = \log 2x + \frac{1}{2\cdot 2x^2} - \frac{3}{2\cdot 4\cdot 4x^4} + \frac{3\cdot 5}{2\cdot 4\cdot 6\cdot 6x^6} + \dots \qquad (x > 1)$$

$$\cosh^{-1} x = \pm\left(\log 2x - \frac{1}{2\cdot 2x^2} - \frac{1\cdot 3}{2\cdot 4\cdot 4x^4} - \frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6\cdot 6x^6} - \dots\right) \qquad (x > 1)$$

$$\tanh^{-1} x = x + \frac{x^3}{3} + \frac{x^5}{5} + \frac{x^7}{7} + \dots \qquad (-1 < x < 1)$$

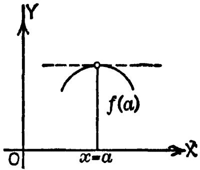
$$\coth^{-1} x = \frac{1}{x} + \frac{1}{3x^3} + \frac{1}{5x^5} + \frac{1}{7x^7} + \dots \qquad (-1 > x > 1)$$

$$\operatorname{sech}^{-1} x = \pm\left(\log \frac{2}{x} - \frac{1}{2\cdot 2}x^2 - \frac{1\cdot 3}{2\cdot 4\cdot 4}x^4 - \frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6\cdot 6}x^6 - \dots\right) \qquad (0 < x < 1)$$

$$\operatorname{csch}^{-1} x = \frac{1}{x} - \frac{1}{2\cdot 3x^3} + \frac{3}{2\cdot 4\cdot 5x^5} - \frac{3\cdot 5}{2\cdot 4\cdot 6\cdot 7x^7} + \dots \qquad (-1 > x > 1)$$

40. MAXIMA AND MINIMA

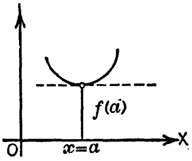
Function of a Single Variable. If a continuous function of x ceases to increase and begins to decrease (Fig. 2), it is said to have a *maximum* value; if the function ceases to decrease and begins to increase (Fig. 3), it is said to have a *minimum* value. A maximum point of a curve is one whose ordinate is algebraically greater than the ordinate of any other point in the immediate neighborhood. A minimum point of a curve is one whose ordinate is algebraically less than the ordinate of any other point in the immediate neighborhood. To find the values of x which give maximum or minimum values of $f(x)$, note that the tangent to the curve at the extreme value is parallel to the OX axis. Then simply solve the equation $f'(x) = 0$.



$f^{(n)}(a)<0$

n even

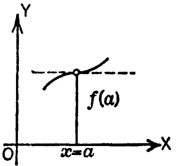
FIG. 2



$f^{(n)}(a)>0$

n even

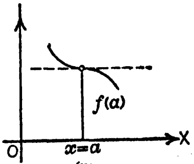
FIG. 3



$f^{(n)}(a)>0$

n odd

FIG. 4



$f^{(n)}(a)<0$

n odd

FIG. 5

If $x = a$ is a solution of this equation, it must be tested to see if it gives a maximum or minimum. To do this, compute the higher derivatives of $f(x)$ until one is found which does not vanish at $x = a$, $f^{(n)}(a) \neq 0$. If its order, n, is an even number, then there is a minimum if $f^{(n)}(a) > 0$, and a maximum if it is < 0. If n is odd, then there is neither a maximum nor minimum, but an inflection point (Figs. 4 and 5). Often, the physical interpretation of the problem will tell whether there is a maximum or minimum when $f'(a) = 0$, and further tests are unnecessary.

Example. A piece of wire of length 30 in. is bent into a rectangle. Find the maximum area. Let x = the length of the base, then $\frac{1}{2}(30 - 2x)$ = the length of the altitude.

The area, $A = x(15 - x) = 15x - x^2$.

For a maxima or minima, $\frac{dA}{dx} = 15 - 2x = 0$, $x = 7.5$.

Then $A = 7.5(15 - 7.5) = 56.25$ sq in.

To find whether the area is maxima or minima, $\frac{d^2A}{dx^2} = -2$ which is less than 0, and therefore the area 56.25 sq in. is a maximum.

Functions of Two or More Independent Variables. The function $f(x, y)$ has a maximum value at (a, b) if $f(a + h, b + k) < f(a, b)$ for all values of $|h|$ and $|k|$ sufficiently small. Likewise, if $f(a + h, b + k) > f(a, b)$, then $f(x, y)$ has a minimum at (a, b). If the function is represented graphically by the surface $z = f(x, y)$, then z has a maximum or minimum value when the tangent plane of the surface is parallel to the XOY plane. Hence, it is necessary that

$$\frac{\partial f}{\partial x} = \frac{\partial f}{\partial y} = 0 \tag{60}$$

If, in addition,

$$\frac{\partial^2 f}{\partial x^2}\frac{\partial^2 f}{\partial y^2} - \left(\frac{\partial^2 f}{\partial x \partial y}\right)^2 > 0 \tag{61}$$

$f(x, y)$ has a maximum value if

$$\frac{\partial^2 f}{\partial x^2} \text{ or } \frac{\partial^2 f}{\partial y^2} < 0 \tag{62}$$

and a minimum value if

$$\frac{\partial^2 f}{\partial x^2} \text{ or } \frac{\partial^2 f}{\partial y^2} > 0 \tag{63}$$

If

$$\frac{\partial^2 f}{\partial x^2}\frac{\partial^2 f}{\partial y^2} - \left(\frac{\partial^2 f}{\partial x \partial y}\right)^2 < 0, \tag{64}$$

then $f(x, y)$ has neither maxima nor minima, and if the expression equals 0, it is doubtful. For a function of several variables $f(x, y, z, \ldots)$, necessary conditions for a maxima or minima are

$$\frac{\partial f}{\partial x} = \frac{\partial f}{\partial y} = \frac{\partial f}{\partial z} = \ldots = 0 \tag{65}$$

INTEGRAL CALCULUS

By M. J. Fish

41. ELEMENTARY PRINCIPLES

Integration is the inverse operation of differentiation. It is indicated by the symbol $\int$ followed by the differential function to be integrated. For example,

$$d(x^3) = 3x^2\,dx \tag{1}$$

and

$$3\int x^2\,dx = x^3 + c \tag{2}$$

or in general

$$\int f'(x)\,dx = f(x) + c \tag{3}$$

where $f(x) + c$ is *indefinite* owing to the necessity of adding the arbitrary constant c whenever the operation of integration is performed.

$$\int_a^b f'(x)\,dx = f(b) - f(a) \tag{4}$$

is called the *definite integral*, where $f'(x)$ is continuous in the interval a to b or has at most a finite number of finite discontinuities in the interval.

Fundamental Forms. Since integration is an anti-differentiation operation, facility in integrating depends upon the ability to recognize the forms of the derivatives of elementary functions and also the knowledge of how to transform a given function into an elementary form. Table I is a list of fundamental forms to which many integrals may be reduced by simple transformation. The constant of integration has been omitted in the tabulation. The integrals of other frequently occurring forms are given in Table 19, Section 1.

Integration by Parts is a method frequently employed if it is advantageous to consider the integral of a function as the integral of the product of a function by the differential of another function; then

$$\int u\,dv = uv - \int v\,du \tag{5}$$

since

$$d(uv) = u\,dv + v\,du \tag{6}$$

where u and v are both functions of a variable x.

Integration of Rational Fractions. If the degree of the numerator is not less than that of the denominator in the equation

$$R(x) = \frac{\phi(x)}{f(x)}$$

where $\phi(x)$ and $f(x)$ are rational polynomials, $R(x)$ can be put in the form of a polynomial and a remainder by performing the division indicated. The remainder may then be represented by partial fractions, see Art. 7, page 2–08, and both the polynomial and remainder integrated directly by application of formulas 1, 2, 15, and 16 in Table I.

Integration of Irrational Functions may frequently be accomplished by reducing them to rational integrals by changing the variable. The method is called integration by rationalization or integration by substitution.

For example, integrals containing the following forms may be rationalized by the substitutions indicated:

Form	*Substitution*
$\int[(ax+b)^{p/q}]\,dx$	let $ax + b = y^q$
$\int[(ax+b)^{p/q}(ax+b)^{r/s}]\,dx$	let $ax + b = y^n$, where n is the L.C.M. of q, s
$\int[x, \sqrt{x^2 + ax + b}]\,dx$	let $\sqrt{x^2 + ax + b} = y - x$
$\int[x, \sqrt{-x^2 + ax + b}]\,dx$	let $\sqrt{-x^2 + ax + b} = \sqrt{(\alpha - x)(\beta + x)}$ $= (\alpha - x)y$ or $= (\beta + x)y$
$\int[\sin x, \cos x]\,dx$	let $\tan\frac{x}{2} = y$
$\int[x, \sqrt{a^2 - x^2}]\,dx$	let $x = a\sin y$
$\int[x, \sqrt{x^2 - a^2}]\,dx$	let $x = a\sec y$ or $x = a\cosh y$
$\int[x, \sqrt{x^2 + a^2}]\,dx$	let $x = a\tan y$ or $x = a\sinh y$

Table I. Fundamental Integrals

1. $\int u^n\,du = \frac{u^{n+1}}{n+1}.$

2. $\int \frac{du}{u} = \log u.$

3. $\int a^u\,du = \frac{a^u}{\log a}.$

4. $\int e^u\,du = e^u.$

5. $\int \cos u du = \sin u.$

6. $\int \sin u du = -\cos u.$

7. $\int \sec^2 u du = \tan u.$

8. $\int \csc^2 u du = -\cot u.$

9. $\int \sec u \tan u du = \sec u.$

10. $\int \csc u \cot u du = -\csc u.$

11. $\int \tan u du = \log \sec u.$
$= -\log \cos u$

12. $\int \cot u du = \log \sin u.$
$= -\log \csc u.$

13. $\int \sec u du = \log(\sec u + \tan u)$
$= \log \tan\left(\frac{\pi}{4} + \frac{u}{2}\right).$

14. $\int \csc u du = \log(\csc u - \cot u)$
$= \log \tan \frac{u}{2}.$

15. $\int \frac{du}{u^2 + a^2} = \frac{1}{a}\tan^{-1}\frac{u}{a},$
$= -\frac{1}{a}\cot^{-1}\frac{u}{a}.$

16. $\int \frac{du}{u^2 - a^2} = \frac{1}{2a}\log\frac{u-a}{u+a},$
$= \frac{1}{2a}\log\frac{a-u}{a+u}$
$= -\frac{1}{a}\tanh^{-1}\frac{u}{a}$ $(u < a)$
$= -\frac{1}{a}\coth^{-1}\frac{u}{a}$ $(u > a).$

17. $\int \frac{du}{\sqrt{a^2 - u^2}} = \sin^{-1}\frac{u}{a},$
$= -\cos^{-1}\frac{u}{a}.$

18. $\int \frac{du}{\sqrt{u^2 \pm a^2}} = \log(u + \sqrt{u^2 \pm a^2})$
$\int \frac{du}{\sqrt{u^2 + a^2}} = \sinh^{-1}\frac{u}{a}$
$\int \frac{du}{\sqrt{u^2 - a^2}} = \cosh^{-1}\frac{u}{a}.$

19. $\int \frac{du}{u\sqrt{u^2 - a^2}} = \frac{1}{a}\sec^{-1}\frac{u}{a},$
$= -\frac{1}{a}\csc^{-1}\frac{u}{a}.$

20. $\int \frac{du}{\sqrt{2au - u^2}} = \text{vers}^{-1}\frac{u}{a}.$

21. $\int \sinh u du = \cosh u.$

22. $\int \cosh u du = \sinh u.$

23. $\int \tanh u du = \log \cosh u.$

24. $\int \coth u du = \log \sinh u.$

25. $\int \text{sech}\, u du = 2\tan^{-1} e^u.$

26. $\int \text{csch}\, u du = \log \tanh \frac{u}{2}.$

In general, with the exception of the square root of polynomials of the second degree, integrals containing fractional powers of polynomials above the first degree cannot be rationalized or integrated in terms of the elementary integral forms.

Elliptic Integrals.* An elliptic integral has the form

$$\int R[x, \sqrt{f(x)}]\,dx$$

where R represents a rational function and $f(x) = a + bx + cx^2 + dx^3 + ex^4$, an algebraic function of the third or fourth degree.

Elliptic Integral of the First Kind.

$$F(\phi, k) = \int_0^x \frac{dx}{\sqrt{(1 - x^2)(1 - k^2x^2)}} = \int_0^\phi \frac{d\phi}{\sqrt{1 - k^2\sin^2\phi}} \quad (k^2 < 1,\ x = \sin\phi) \tag{8}$$

Elliptic Integral of the Second Kind.

$$B(\phi, k) = \int_0^x \frac{\sqrt{1 - k^2x^2}}{\sqrt{1 - x^2}}\,dx = \int_0^\phi \sqrt{1 - k^2\sin^2\phi}\,d\phi \quad (k^2 < 1,\ x = \sin\phi) \tag{9}$$

Elliptic Integral of the Third Kind.

$$E(\phi, k) = \int_0^x \frac{dx}{(x^2 - a)\sqrt{(1 - x^2)(1 - k^2x^2)}} = \int_0^\phi \frac{d\phi}{(\sin^2\phi - a)\sqrt{1 - k^2\sin^2\phi}} \quad (k^2 < 1,\ x = \sin\phi) \tag{10}$$

---

* Reference: Smithsonian Mathematical Formulae and Tables of Elliptic Functions by E. P. Adams and R. L. Hippisley. 1922, Washington, D. C.

The "complete" integrals are

$$K = F\left(\frac{\pi}{2}, k\right), \qquad E = E\left(\frac{\pi}{2}, k\right)$$

$$K' = F\left(\frac{\pi}{2}, \sqrt{1-k^2}\right), \qquad E' = E\left(\frac{\pi}{2}, \sqrt{1-k^2}\right) \tag{11}$$

where $K = F\left(\frac{\pi}{2}, k\right) = \int_0^1 \frac{dx}{\sqrt{(1-x^2)(1-k^2x^2)}} = \int_0^{\pi/2} \frac{d\phi}{\sqrt{1-k^2\sin^2\phi}}$

and $$KE + EK' - KK' = \frac{\pi}{2}$$

$$K = \frac{\pi}{2}\left[1 + \left(\frac{1}{2}\right)^2 k^2 + \left(\frac{3}{2\cdot 4}\right)^2 k^4 + \left(\frac{3\cdot 5}{2\cdot 4\cdot 6}\right)^3 k^6 + \ldots\right] \tag{12}$$

$$E = \frac{\pi}{2}\left[1 - \left(\frac{1}{2^2}\right) k^2 - \left(\frac{3}{2^2\cdot 4^2}\right) k^4 - \left(\frac{3^2\cdot 5}{2^2\cdot 4^2\cdot 6^2}\right) k^6 - \ldots\right] \tag{13}$$

The inverse function of $u = F(\phi, k)$ is $\phi = \text{am } u$, (am = amplitude)

$$x \equiv \sin\phi \equiv \text{sn } u = u - (1+k^2)\frac{u^3}{3!} + (1 + 14k^2 + k^4)\frac{u^5}{5!} - \ldots \tag{14}$$

$$\cos\phi \equiv \text{cn } u = 1 - \frac{u^2}{2!} + (1+4k^2)\frac{u^4}{4!} - (1 + 44k^2 + 16k^4)\frac{u^6}{6!} + \ldots \tag{15}$$

$$\sqrt{1-k^2x^2} \equiv \Delta\phi \equiv \text{dn } u = 1 - k^2\frac{u^2}{2!} + k^2(4+k^2)\frac{u^4}{4!} - k^2(16 + 44k^2 + k^4)\frac{u^6}{6!} + \ldots \tag{16}$$

42. DEFINITE INTEGRALS

Definite Integral. The definite integral is denoted by

$$\int_a^b f(x)\, dx \tag{17}$$

and represents the

$$\lim_{n\to\infty} \sum_{\nu=1}^{n} f(\xi_\nu)\,\Delta x_\nu \tag{18}$$

that is, the limit of the sum of

$$f(\xi_1)\Delta x_1 + f(\xi_2)\Delta x_2 + \ldots + f(\xi_n)\Delta x_n \text{ as } n \to \infty \text{ and } \Delta x_\nu \to 0. \tag{19}$$

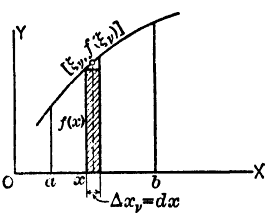


FIG. 1

The interval of integration $a \leqq x \leqq b$ is partitioned into n arbitrary parts $\Delta x_1, \Delta x_2, \ldots, \Delta x_n$, so that $\Delta x_1 + \Delta x_2 + \ldots + \Delta x_n = b - a$. ξ_ν represents an arbitrary value of x in the interval Δx_ν; the limit is to be taken as $n \to \infty$ and $\Delta x_\nu \to 0$.

The geometric interpretation of the definite integral is the area under the curve $y = f(x)$, if $f(x) \geqq 0$, between the x axis and the ordinates at $x = a$ and $x = b$. $f(x)\,dx$ represents the area of a parallelogram of height $f(x)$ and width dx (Fig. 1). If $f(x)$ is a continuous function or has only a finite number of finite discontinuities (jumps), the integral above exists and

$$\frac{d}{dx}\int_a^x f(x)\,dx = \frac{d}{dx}\int_a^x f(u)\,du = f(x) \tag{20}$$

For the purposes of evaluating a definite integral,

$$\text{if } F(x) = \int f(x)\,dx, \text{ then} \int_a^b f(x)\,dx = F(b) - F(a) \tag{21}$$

For example, $\int_3^5 x^2\,dx = \left[\frac{x^3}{3}\right]_3^5 = \frac{125}{3} - 9 = \frac{98}{3}$.

Some Fundamental Theorems.

$$\int_a^b [f_1(x) + f_2(x) + \ldots + f_n(x)]\,dx = \int_a^b f_1(x)\,dx + \int_a^b f_2(x)\,dx + \ldots + \int_a^b f_n(x)\,dx \tag{22}$$

$$\int_a^b f(x)\,dx = -\int_b^a f(x)\,dx \tag{23}$$

$$\int_a^b f(x)\,dx = \int_a^c f(x)\,dx + \int_c^b f(x)\,dx \qquad (a \leqq c \leqq b) \tag{24}$$

$\int_a^b f(x)\,dx = (b - a)f(\xi)$ where ξ is some value between a and b (mean value theorem) (25)

Simpson's Rule for Approximate Integration. This is a method for obtaining the approximate value of the definite integral of a continuous function when the integral can not be evaluated in elementary functions. Given the integral $\int_a^b f(x)\,dx$ which is to be evaluated. Plot the curve $f(x)$, and divide the interval into n equal parts (n = even), erecting the ordinates $y_0, y_1, \ldots, y_n$ as shown (Fig. 2). Then *Simpson's rule* states that

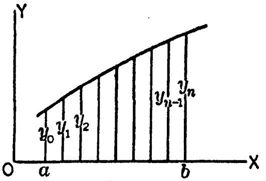

FIG. 2

$$\int_a^b f(x)\,dx = \frac{b-a}{3n}(y_0 + 4y_1 + 2y_2 + 4y_3 + 2y_4 + \ldots + 4y_{n-1} + y_n) \tag{26}$$

Multiple Integrals. Given a region R in the XOY plane and let it be divided into rectangles by the lines

$$\left.\begin{array}{ll} x = x_i & (i = 0, 1, 2, \ldots, n) \\ y = y_k & (k = 0, 1, 2, \ldots, m) \end{array}\right\} \tag{27}$$

Consider any rectangle, with dimensions $x_{i+1} - x_i$ and $y_{k+1} - y_k$, which lies either wholly or partly in R, and let (ξ_i, η_k) be any point in this rectangle or in R if the rectangle extends outside of R. Let $f(x, y)$ be any function which is continuous in R. Then the limit of the double sum

$$\sum_{i=0}^{n}\sum_{k=0}^{m} f(\xi_i, \eta_k)(x_{i+1} - x_i)(y_{k-1} - y_k) \tag{28}$$

as n and m both $\rightarrow \infty$ and each of the differences $x_{i+1} - x_i$ and $y_{k+1} - y_k \rightarrow 0$ is expressed by the formula

$$\iint_R f(x, y)\,dx\,dy \tag{29}$$

which may be written as

$$\iint_R f(x, y)\,dA, \tag{30}$$

where dA is the element of area.

In case polar coordinates (r, θ) are used instead of (x, y), then $f(x, y)$ is replaced by $F(r, \theta)$ and $dA = dx\,dy$ by $r d\theta\,dr$.

The analogous triple integral in space is

$$\iiint_R f(x, y, z)\,dx\,dy\,dz \tag{31}$$

which may be written as

$$\iiint_R f(x, y, z)\,dV \tag{32}$$

where dV is the element of volume.

If spherical coordinates (r, θ, ϕ) are used instead of (x, y, z), then $f(x, y, z)$ is replaced by $F(r, \theta, \phi)$ and $dV = dx\,dy\,dz$ by $r^2 \sin\phi\,d\theta\,d\phi\,dr$. If cylindrical coordinates (r, θ, z) are used instead of (x, y, z), then $f(x, y, z)$ is replaced by $G(r, \theta, z)$ and $dx\,dy\,dz$ by $r d\theta\,dr\,dz$.

Improper Integrals. It may happen that the interval of integration becomes *infinite*, that the integral itself becomes infinite at certain points, or that both occur. In such cases the integral may have a definition.

Case in Which One of the Limits is Infinite. By definition,

$$\int_a^\infty f(x)dx = \lim_{b\rightarrow\infty} \int_a^b f(x)dx$$

If the expression on the right has a definite value, then so does the expression on the left which is then said to converge. A rule to determine when this is so is as follows: if the integral $\int_a^\infty f(x)dx$ is written in the form

$$\int_a^\infty \frac{g(x)}{x^k}\,dx, \tag{33}$$

then if $|g(x)| < M$, a constant, for arbitrarily large values of x and $k > 1$, the integral *converges*; however, if $|g(x)| > m$, an arbitrary positive constant, for sufficiently large values of x and $k \leqq 1$, the integral *diverges*.

Example. Test $\int_0^\infty \frac{xdx}{(ax + x^2)^{3/2}}$ for convergence or divergence.

$$\int_0^\infty \frac{xdx}{(ax + x^2)^{3/2}} = \int_0^\infty \left(\frac{x^2}{ax + x^2}\right)^{3/2} \frac{dx}{x^2},$$

where $g(x) = \left(\frac{x^2}{ax + x^2}\right)^{3/2}$ which approaches the limit 1 as $x \to \infty$, and $k = 2 > 1$. (See Indeterminate Forms.) Therefore the integral converges.

Case in Which the Integrand Is Infinite. Consider the case in which the integrand becomes infinite at the upper limit. For, if the integrand becomes infinite at the lower limit, the limits may be reversed by a change of sign; and if the integrand becomes infinite at an intermediate point, the formula (24)

$$\int_a^b f(x)dx = \int_a^c f(x)dx + \int_c^b f(x)dx \qquad (a < c < b) \tag{34}$$

may be used. Then, if $f(b) \to \infty$, by definition,

$$\int_a^b f(x)dx = \lim_{\epsilon \to 0} \int_a^{b-\epsilon} f(x)dx \tag{35}$$

where ϵ is a small positive quantity. If the limit exists, the integral is said to converge. A rule to determine when this is so, is as follows: if the integral $\int_a^b f(x)dx$ is written in the form

$$\int_a^b \frac{g(x)}{(b - x)^k}\,dx \tag{36}$$

then for values of x sufficiently near b, if $|g(x)| < M$, a constant, and $k < 1$, the integral converges; however, for values of x sufficiently near b, if $|g(x)| > m$, a constant, and $k \geqq 1$, the integral diverges.

Example. Test $\int_0^1 \log_e x\,dx$ for convergence or divergence.

The integrand is infinite at $x = 0$. Let $\int_0^1 \log_e x\,dx = \int_0^1 \frac{x^{1/2}\log_e x}{x^{1/2}}\,dx$, where $g(x) = x^{1/2}\log_e x$ which tends to zero as $x \to 0$. Since $k = 1/2 < 1$, the integral converges.

Integrals Containing a Parameter. Consider

$$\phi(\alpha) = \int_{x_0}^{x_1} f(x, \alpha)dx, \tag{37}$$

a definite integral in which the integrand contains the parameter α. As an example,

$$\int_0^{\pi/2} \cos\alpha x\,dx = \left[\frac{1}{\alpha}\sin\alpha x\right]_0^{\pi/2} = \frac{1}{\alpha} \tag{38}$$

The indefinite integral is a function of x and α, while the definite integral is a function of α alone. The function $f(x, \alpha)$ may be plotted as the surface $z = f(x, \alpha)$ over the rectangle of values (x, α) where $x_0 \leqq x \leqq x_1$ and $\alpha_0 \leqq \alpha \leqq \alpha_1$. The value $\phi(\alpha_i)$ of the function when $\alpha = \alpha_i$ is then the area of the section shown made by the plane $\alpha = \alpha_i$ (Fig. 3). The function $\phi(\alpha)$ is continuous if $f(x, \alpha)$ is continuous in the two variables x and α. In case the limits of the integral are functions of α, as

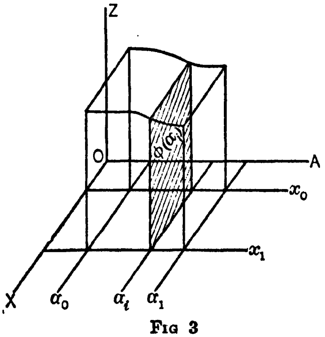

Fig 3

$$\phi(\alpha) = \int_{x_0 = g_0(\alpha)}^{x_1 = g_1(\alpha)} f(x, \alpha)dx, \qquad \alpha_0 \leqq \alpha \leqq \alpha_1 \tag{39}$$

the function $\phi(\alpha)$ is continuous if $f(x, \alpha)$ is continuous over the region bounded by the lines $\alpha = \alpha_0$, $\alpha = \alpha_1$ and the curves $x_0 = g_0(\alpha)$, $x_1 = g_1(\alpha)$, and if the functions $g_0(\alpha)$ and $g_1(\alpha)$ are continuous.

Uniform Convergence of Integrals. An integral is uniformly convergent if, for a positive number ϵ, which can be made arbitrarily small, there corresponds another number L, such that

$$\left| \int_l^\infty f(x, \alpha)d\alpha \right| < \epsilon \tag{40}$$

provided that $l \geqq L$ where the number L is the same for every value of α in the interval $\alpha_0 \leqq \alpha \leqq \alpha_1$.

Differentiation under the Integral Sign. If $f(x)$ is a continuous function of x for $x = a$ or $x = b$, then

$$\frac{\partial}{\partial b}\int_a^b f(x)dx = f(b), \quad \frac{\partial}{\partial a}\int_a^b f(x)dx = -f(a) \tag{41}$$

If $\phi(\alpha) = \int_a^b f(x, \alpha)dx$, then $\frac{d\phi}{d\alpha} = \int_a^b \frac{\partial f(x, \alpha)}{\partial \alpha}dx$, where $f(x, \alpha)$ is a continuous function of x and α between the limits $a \leqq x \leqq b$, $\alpha_0 \leqq \alpha \leqq \alpha_1$, and in addition $\frac{\partial f}{\partial \alpha}$ exists and is continuous. In case the limits of the integral are functions of α, as

$$\phi(\alpha) = \int_{x_0 = g_0(\alpha)}^{x_1 = g_1(\alpha)} f(x, \alpha)dx \tag{42}$$

then

$$\frac{d\phi}{d\alpha} = \int_{g_0(\alpha)}^{g_1(\alpha)} \frac{\partial f(x, \alpha)}{\partial \alpha}dx - f(g_0, \alpha)\frac{dg_0}{d\alpha} + f(g_1, \alpha)\frac{dg_1}{d\alpha} \tag{43}$$

where $\frac{\partial f}{\partial \alpha}$ exists and is continuous and where $g_0(\alpha)$, $g_1(\alpha)$ are differentiable. The formula for differentiation under the integral sign can be applied where the integral obtained is uniformly convergent in the interval of definition; that is, if

$$\phi(\alpha) = \int_a^b f(x, \alpha)\,dx, \qquad \alpha_0 \leqq \alpha \leqq \alpha_1 \tag{44}$$

and in addition

$$\frac{d\phi}{d\alpha} = \int_a^b \frac{\partial f(x, \alpha)}{\partial \alpha}dx \tag{45}$$

is uniformly convergent. The process of differentiating under the integral sign is sometimes of use in evaluating the function $\phi(\alpha)$.

Example. Given $\phi(\alpha) = \int_0^1 \frac{x^\alpha - 1}{\log_e x}dx$.

$$\frac{d\phi}{d\alpha} = \int_0^1 \frac{x^\alpha \log_e x}{\log_e x}dx = \int_0^1 x^\alpha\,dx = \left[\frac{1}{\alpha+1}x^{\alpha+1}\right]_0^1 = \frac{1}{\alpha+1} \quad \text{and} \quad \phi(\alpha) = \log_e(\alpha+1) + C.$$

But $\phi(0) = \int_0^1 0\,dx = 0$, and $\phi(0) = \log_e 1 + C$. Therefore $C = 0$.

Hence

$$\phi(\alpha) = \int_0^1 \frac{x^\alpha - 1}{\log_e x}dx = \log_e(\alpha + 1).$$

Integration under the Integral Sign. Let $f(x, \alpha)$ be a function of two variables, continuous in the region defined by $a \leqq x \leqq b$, $\alpha_0 \leqq \alpha \leqq \alpha_1$, where a, b, α_0, α_1 are constants. The inversion of the order of integration

$$\int_a^b dx\int_{\alpha_0}^{\alpha_1} f(x, \alpha)d\alpha = \int_{\alpha_0}^{\alpha_1} d\alpha\int_a^b f(x, \alpha)\,dx \tag{46}$$

is the formula for integration under the integral sign and is valid under the conditions stated above.

The case of integration under the integral sign with infinite limits is valid if the integral $\int_a^{+\infty} f(x, \alpha)dx$ is uniformly convergent in $\alpha_0 \leqq \alpha \leqq \alpha_1$, and the formula is

$$\int_a^{+\infty} dx\int_{\alpha_0}^{\alpha_1} f(x, \alpha)d\alpha = \int_{\alpha_0}^{\alpha_1} d\alpha\int_a^{+\infty} f(x, \alpha)dx \tag{47}$$

The method of integration under the integral sign is sometimes useful for evaluating definite integrals.

Example. Consider $\int_0^1 x^\alpha\, dx = \frac{1}{\alpha + 1}$ $(\alpha + 1 > 0)$.

Multiply by $d\alpha$ and integrate between the limits c and d.

$$\int_c^d d\alpha \int_0^1 x^\alpha\, dx = \int_c^d \frac{d\alpha}{\alpha + 1} = \log_e \frac{d+1}{c+1}$$

but $$\int_0^1 dx \int_c^d x^\alpha\, d\alpha = \int_0^1 \frac{x^d - x^c}{\log_e x}\, dx; \quad \text{therefore} \int_0^1 \frac{x^d - x^c}{\log_e x}\, dx = \log_e \frac{d+1}{c+1}$$

Example. Consider $f(x, y) = \frac{x^2 - y^2}{(x^2 + y^2)^2}$.

Applying the formula above $\int_0^1 dx \int_0^1 \frac{x^2 - y^2}{(x^2 + y^2)^2}\, dy = \int_0^1 dy \int_0^1 \frac{x^2 - y^2}{(x^2 + y^2)^2}\, dx$.

A first integration for the expression on the left, $\int_0^1 \frac{x^2 - y^2}{(x^2 + y^2)^2}\, dy = \left[\frac{y}{x^2 + y^2}\right]_0^1 = \frac{1}{1 + x^2}$.

Then $$\int_0^1 \frac{dx}{1 + x^2} = \left[\tan^{-1} x\right]_0^1 = \frac{\pi}{4}$$

In integrating the expression on the right $\int_0^1 \frac{x^2 - y^2}{(x^2 + y^2)^2}\, dx = \left[-\frac{x}{x^2 + y^2}\right]_0^1 = -\frac{1}{1 + y^2}$; $-\int_0^1 \frac{dy}{1 + y^2} = -\frac{\pi}{4}$. The results are not equal since the function $\frac{x^2 - y^2}{(x^2 + y^2)^2}$ is discontinuous at $x = 0$, $y = 0$.

43. LINE, SURFACE, AND VOLUME INTEGRALS

Line Integrals. Consider a plane curve C, defined by the two parametric equations $x = f(t)$, $y = \phi(t)$. By varying t from a to b, a certain arc AB of this curve is obtained. Suppose that $a < b$, and take between a and b a sequence of increasing numbers $(a = t_0 < t_1 < t_2 < \ldots t_{n-1} < t_n = b)$, and in each partial interval (t_{i-1}, t_i) take any value θ_i such that $t_{i-1} \leqq \theta_i \leqq t_i$. Let (x_i, y_i) be the coordinates of the point of C which corresponds to the value t_i of the parameter; let (ξ_i, η_i) be the coordinates of the point which corresponds to the value θ_i. Let $P(x, y)$ be a function of the two variables x and y which is continuous along the arc AB.

Consider the sum

$$\sum_{i=1}^{n} P(\xi_i, \eta_i)(x_i - x_{i-1}) \equiv P(\xi_1, \eta_1)(x_1 - x_0) + P(\xi_2, \eta_2)(x_2 - x_1) + \ldots + P(\xi_n, \eta_n)(x_n - x_{n-1}) \tag{48}$$

extended to all the partial intervals. If the number n of the subdivisions increases indefinitely in such a manner that the largest of the differences $t_i - t_{i-1}$ tends toward zero, the preceding sum tends toward a limit, which is called the line integral of the function $P(x, y)$ along the arc AB and is represented by the symbol

$$\int_{(AB)} P(x, y)\, dx \tag{49}$$

Suppose that the curve is one as $ACDB$ in Fig. 4 on which are found two points C and D where the abscissa is a maximum or minimum. Then each of the arcs AC, CD, DB satisfies the preceding conditions, and

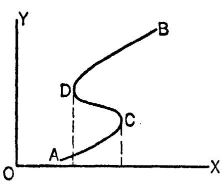

FIG. 4

$$\int_{(ACDB)} P(x, y)dx = \int_{(AC)} P(x, y)dx + \int_{(CD)} P(x, y)dx + \int_{(DB)} P(x, y)dx \tag{50}$$

A discussion similar to that above can be made for the line integral $\int_{(AB)} Q(x, y)dy$, but it is more common to find line integrals occurring in the form

$$\underset{(C)}{\int_{a,\, b}^{x,\, y}} [P(x, y)dx + Q(x, y)dy] \tag{51}$$

where $y = f(x)$. This is the line integral along the curve C or $y = f(x)$ from the point (a, b) to the point (x, y).

As an example of the application of the line integral, consider the work done by a force on a particle. By definition, the work done by a constant force F acting on a particle which moves a distance s along a straight line inclined at an angle θ to the force is $W = Fs \cos \theta$. If the path is curvilinear and the force variable, the differential of work is $dW = F \cos \theta \, ds$, where ds is the infinitesimal arc. Hence

$$W = \int dW = \int_{a,\,b}^{x,\,y} F \cos \theta \, ds \tag{52}$$

where the path must be known to evaluate the integral (Fig. 5).

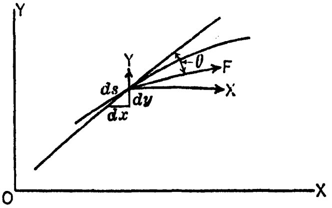

Fig. 5

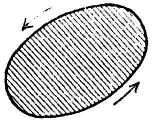
Example. Find the value of $\int_{0,\,0}^{1,\,3} [y^2\,dx + (xy - x^2)dy]$ along the paths (a) $y = 3x$, (b) $y^2 = 9x$.

(a) Substitute $y = 3x$, $dy = 3dx$ and obtain $\int_0^1 [9x^2 + (3x^2 - x^2)3]\,dx = \int_0^1 15x^2 = 5$.

(b) Substitute $y^2 = 9x$, $2y\,dy = 9dx$ and obtain $\int_0^3 \left[\frac{2}{9}y^3 + \left(\frac{y^3}{9} - \frac{y^4}{81}\right)\right]dy = \left[\frac{1}{12}y^4 - \frac{y^5}{405}\right]_0^3$ $= 6\,3/20$.

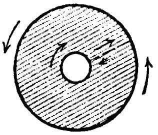
Connectivity of Regions. A region is called simply connected if every closed curve or surface in the region can be shrunk to a point without passing outside of the region. In the section of a plane between two concentric circles a curve surrounding the inner curve cannot be shrunk to a point. Such a region is called multiply connected.

A multiply connected region can be made simply connected by the following procedure. Suppose that, in the region in Fig. 7, a line is drawn connecting the two bounding circles and it is agreed that no curve shall cross this line. Then the entire region would be surrounded by a single boundary, part of which would be counted twice. In like manner, the region in Fig. 8 can be made simply connected by two such lines or cuts as they are called. The number of cuts which is necessary to reduce the region to two simply connected regions is called the connectivity. Thus, in Fig. 7, two cuts would make two simply connected regions out of the original region.



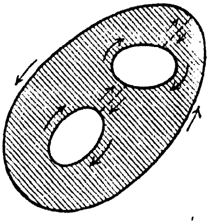
Simply Connected Region

Fig. 6



Doubly Connected Region

Fig. 7



Triply Connected Region

Fig. 8

In using line integrals about closed curves, in order to distinguish between the two directions in which a curve may be traversed, it is customary to say that the positive direction is that in which a person walking about the curve would have the region on his left. In Figs. 6, 7, 8, the arrows show the positive direction.

Area Expressed as a Line Integral. Given a region of area A bounded by a closed curve C, such that a line parallel to OX or OY meets the region in two points or not at all (points of tangency to be counted twice). Then

$$A = {}^1/_2 \int (x\,dy - y\,dx) \tag{53}$$

where the line integral is to be taken around the boundary of the area. The formula is

also true for areas which can be cut up into areas of the simple type shown in Fig. 9. Thus the area of a region as shown in Fig. 10 or that of a multiply connected region can be reduced to the above type.

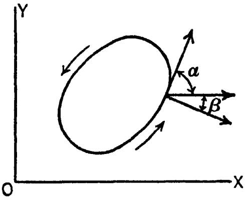


Fig. 9

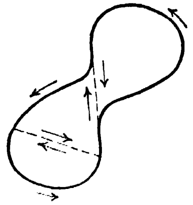

Fig. 10

Example. The area of the ellipse represented by the formulas

$$x = a\cos t, \quad y = b\sin t$$

has the expression $A = {}^1\!/_2\int_0^{2\pi} ab(\cos^2 t + \sin^2 t)dt = \pi ab.$

Area of Curved Surface. Given a curved surface defined by the equations

$$x = \phi(u, v),\ y = \psi(u, v),\ z = f(u, v) \tag{54}$$

The area of any portion of the surface is defined as the integral

$$S = \int\int \sqrt{EG - F^2}\,du\,dv \tag{55}$$

the integration to be extended over values of u and v corresponding to the portion of the surface considered. In the above formula

$$E = \left(\frac{\partial x}{\partial u}\right)^2 + \left(\frac{\partial y}{\partial u}\right)^2 + \left(\frac{\partial z}{\partial u}\right)^2,\ F = \frac{\partial x}{\partial u}\frac{\partial x}{\partial v} + \frac{\partial y}{\partial u}\frac{\partial y}{\partial v} + \frac{\partial z}{\partial u}\frac{\partial z}{\partial v},\ G = \left(\frac{\partial x}{\partial v}\right)^2 + \left(\frac{\partial y}{\partial v}\right)^2 + \left(\frac{\partial z}{\partial v}\right)^2 \tag{56}$$

Example. A sphere of radius r is defined by the equations

$$x = r\cos\theta\sin\phi,\ y = r\sin\theta\sin\phi,\ z = r\cos\phi$$

in spherical coordinates. Then

$$E = r^2\sin^2\phi,\ F = 0,\ G = r^2 \text{ and } S = \int_0^{2\pi}\int_0^{2\pi} r^2\sin\phi\,d\phi\,d\theta = 4\pi r^2$$

A surface $z = f(x, y)$ is the special case of (54) in which $x = u,\ y = v,\ z = f(u, v) = f(x,y)$. Let α, β, γ be the angles made by the normal to the surface at the point (x, y, z) with OX, OY, OZ, respectively. Then

$$S = \int \sec\gamma\,dx\,dy = \int\int\sqrt{1 + \left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2}\,dx\,dy \tag{57}$$

Similarly, the surfaces $y = \psi(z, x)$ and $x = \phi(y, z)$ give

$$S = \int \sec\beta\,dz\,dx = \int\int\sqrt{1 + \left(\frac{\partial y}{\partial z}\right)^2 + \left(\frac{\partial y}{\partial x}\right)^2}\,dz\,dx \tag{58}$$

and

$$S = \int \sec\alpha\,dy\,dz = \int\int\sqrt{1 + \left(\frac{\partial x}{\partial y}\right)^2 + \left(\frac{\partial x}{\partial z}\right)^2}\,dy\,dz \tag{59}$$

Example. Find the area of the surface cut from the cylinder $y^2 + z^2 = a^2$ by the cylinder $x^2 + y^2 = a^2$.

$$z = \sqrt{a^2 - y^2},\ \frac{\partial z}{\partial x} = p = 0,\ \frac{\partial z}{\partial y} = q = -\frac{y}{\sqrt{a^2 - y^2}}$$

The element of surface $dS = \sqrt{1 + p^2 + q^2}\,dx\,dy = \dfrac{a}{\sqrt{a^2 - y^2}}\,dx\,dy$

$$S = 8\int_0^a\int_0^{\sqrt{a^2-y^2}} \frac{a}{\sqrt{a^2 - y^2}}\,dx\,dy = 8\int_0^a a\,dy = 8a^2$$

where the limits are taken over one-eighth of the surface cut out.

Surface Integrals. A surface integral may be defined in a similar manner to the line integral; if a surface $z = f(x, y)$ is divided into elements of area ΔS_i and the value of the function $F(x, y, z)$ is taken at any point (ξ_i, η_i, ζ_i) of the element, and the sum $\Sigma F(\xi_i, \eta_i, \zeta_i)\Delta S_i$ is extended over all the elements, the limit of the sum of elements, as the number n of elements increases indefinitely and the elements become small in every direction, is defined as the surface integral of the function F over the surface.

This may be written

$$\lim_{n \to \infty} \sum_{i=1}^{n} F(\xi_i, \eta_i, \zeta_i)\Delta S_i = \int F dS = \int\int F(x, y, z) \sqrt{1 + \left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2}\, dx\, dy \quad (60)$$

Since $dS = \sec \alpha\, dy\, dz = \sec \beta\, dz\, dx = \sec \gamma\, dx\, dy$, (60) can be written

$$\int\int F(x, y, z) \sec \alpha\, dy\, dz, \int\int F(x, y, z) \sec \beta\, dz\, dx, \text{ or} \int\int F(x, y, z) \sec \gamma\, dx\, dy \quad (60a)$$

If we set $F(x, y, z) \sec \alpha = P(x, y, z)$, $F(x, y, z) \sec \beta = Q(x, y, z)$, $F(x, y, z) \sec \gamma = R(x, y, z)$, we have

$$\int\int P(x, y, z)\, dy\, dz, \int\int Q(x, y, z) dz\, dx, \text{ or} \int\int R(x, y, z)\, dx\, dy \quad (60b)$$

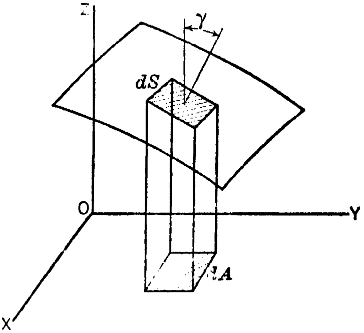

FIG. 11

In applications, it is common to find surface integrals occurring in the form $\int\int (P\ dy\, dz + Q\ dx\ dz + R dx\ dy)$ which is equal to $\int\int (P \cos \alpha + Q \cos \beta + R \cos \gamma) dS$.

Green's Theorem. This is a method whereby a line integral around a closed curve may be stepped up into a surface integral which spans the curve, or a surface integral may be stepped up into a volume integral. Consider a simply connected region R bounded by a closed curve C of the type allowed for line integrals and let $P(x, y)$ and $Q(x, y)$ be continuous functions of x, y with continuous partial derivatives $\frac{\partial P}{\partial y}$ and $\frac{\partial Q}{\partial x}$ over this region. Then

$$\int\int_{(R)} \left(\frac{\partial P}{\partial y} - \frac{\partial Q}{\partial x}\right) dx\, dy = - \int_{(C)} (P dx + Q dy) \quad (61)$$

This result can be extended to regions of more complicated form. Green's theorem is sometimes found written in other forms. Referring to Fig. 9, let α be the angle made with OX by the positive direction of C, and β be the angle made with OX by the normal drawn outward. Then if F is a function of (x, y) and $\frac{dF}{dn}$ is its derivative in the direction of the outward normal,

$$\frac{dF}{dn} = \frac{\partial F}{\partial x}\frac{dy}{ds} - \frac{\partial F}{\partial y}\frac{dx}{ds} = \frac{\partial F}{\partial x} \cos \beta + \frac{dF}{dy} \sin \beta \quad (62)$$

where s is the arc length of the curve.

Let $P = \frac{\partial F}{\partial y}$, $Q = -\frac{\partial F}{\partial x}$, then (61) may be written as

$$\int\int_{(R)} \left(\frac{\partial^2 F}{\partial x^2} + \frac{\partial^2 F}{\partial y^2}\right) dx\, dy = \int_{(C)} \left(\frac{\partial F}{\partial x} dy - \frac{\partial F}{\partial y} dx\right) = \int_{(C)} \frac{dF}{dn} ds \quad (63)$$

In space, the analogous formulas are

$$\int\int\int_{(V)} \left[\frac{\partial P(x, y, z)}{\partial x} + \frac{\partial Q(x, y, z)}{\partial y} + \frac{\partial R(x, y, z)}{\partial z}\right] dx\, dy\, dz$$

$$= \int\int_{(S)} (P \cos \alpha + Q \cos \beta + R \cos \gamma)\, dS = \int\int_{(S')} (P\ dy\ dz + Q\ dz\ dx + R\ dx\ dy) \quad (64)$$

where the triple integral is to be taken over the volume V of the region, the first double integral over the bounding surface S of the region, and the second double integral is taken over the projections of the bounding surface on the planes YOZ, XOZ, XOY, respectively. The signs of the cosines are to be determined as is customary, with the outward normal as the positive direction.

Example. Apply Green's theorem to $\int\int (x\, dy\, dz + y\, dz\, dx + z\, dx\, dy)$ over the cylinder

$$x^2 + y^2 = a^2, \quad z = \pm b.$$

Since $$P = x, \quad Q = y, \quad R = z; \quad \frac{\partial P}{\partial x} = 1, \frac{\partial Q}{\partial y} = 1, \frac{\partial R}{\partial z} = 1,$$

and $$\int_{-a}^{a} \int_{-\sqrt{a^2 - x^2}}^{\sqrt{a^2 - x^2}} \int_{-b}^{+b} 3\, dx\, dy\, dz = 6\pi a^2 b.$$

Stokes' Theorem. This theorem is a method of expressing the integral around a closed curve in space as an integral over a surface having that curve as a boundary; namely,

$$\int_{(C)} [P(x, y, z)\,dx + Q(x, y, z)\,dy + R(x, y, z)\,dz]$$
$$= -\iint_{(S)} \left[\left(\frac{\partial Q}{\partial z} - \frac{\partial R}{\partial y}\right)\cos\alpha + \left(\frac{\partial R}{\partial x} - \frac{\partial P}{\partial z}\right)\cos\beta + \left(\frac{\partial P}{\partial y} - \frac{\partial Q}{\partial x}\right)\cos\gamma\right] dS \quad (65)$$

where C is the space curve and S is the surface which it bounds. The signs are such that an observer standing with his feet on the surface and head in the direction of the normal will see the integration around C taken in the positive direction.

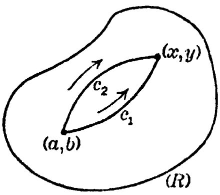

FIG. 12

Independence of Path and Exact Differential. Given a simply connected region R, bounded by a closed curve of the type allowed for line integrals, and let $P(x, y)$ and $Q(x, y)$ be continuous functions of (x, y) over this region with the partial differentials $\frac{\partial P}{\partial y}$ and $\frac{\partial Q}{\partial x}$, single valued and continuous. Then if the line integrals from (a, b) to (x, y) along the two paths

$$\underset{(c_1)}{\int_{a,b}^{x,y}} (P\,dx + Q\,dy) = \underset{(c_2)}{\int_{a,b}^{x,y}} (P\,dx + Q\,dy) \quad (66)$$

are equal, the line integral around the combined path c

$$\underset{(c_1)}{\int_{a,b}^{x,y}} (P\,dx + Q\,dy) + \underset{(c_2)}{\int_{x,y}^{a,b}} (P\,dx + Q\,dy)$$
$$= \underset{(c)}{\int} (P\,dx + Q\,dy) = 0 \text{ vanishes (Fig. 12).} \quad (67)$$

By making use of Green's theorem, it may be stated that, in a simply connected region in which P, Q, and their first partial derivatives are continuous, a necessary and sufficient condition that the integral $\int (P\,dx + Q\,dy)$ around any closed path should be zero and that the integral along a path connecting the two points be independent of the path is $\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}$. In three dimensions, similar conditions for

$$\int_{a,b,c}^{x,y,z} (P\,dx + Q\,dy + R\,dz) \quad (68)$$

are that
$$\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x},\ \frac{\partial Q}{\partial z} = \frac{\partial R}{\partial y},\ \frac{\partial R}{\partial x} = \frac{\partial P}{\partial z}. \quad (69)$$

The condition $\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}$ is a necessary and sufficient condition that $P\,dx + Q\,dy$ be the exact differential of some function $\phi(x, y)$ as well as that the line integral $\underset{(c_1)}{\int_{a,b}^{x,y}} d\phi$ be independent of the path.

Example. Consider $\int \left[\frac{2x - y}{x^2 + y^2}\,dx + \frac{2y + x}{x^2 + y^2}\,dy\right]$.

Here $\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x} = \frac{y^2 - 4xy - x^2}{(x^2 + y^2)^2}$, and the condition is met, but P and Q and their derivatives are discontinuous at the origin and hence the theorem may be applied only to simply connected regions which do not contain the origin. That is, the integrals along any two paths which do not enclose the origin are the same, but the integrals along two paths which do enclose the origin are not necessarily the same.

44. SOME APPLICATIONS OF INTEGRATION

Length of Arc of a Curve. The length s of the arc of a plane curve $y = f(x)$ from the point (a, b) to the point (c, d) is

$$s = \int_a^c \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\,dx = \int_b^d \sqrt{1 + \left(\frac{dx}{dy}\right)^2}\,dy \quad (70)$$

If the equation of the curve is in polar coordinates, $r = f(\theta)$, then the length of the arc from the point (r_1, θ_1) to the point (r_2, θ_2) is

$$s = \int_{\theta_1}^{\theta_2} \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2}\, d\theta = \int_{r_1}^{r_2} \sqrt{1 + r^2\left(\frac{d\theta}{dr}\right)^2}\, dr \tag{71}$$

If the curve is in three dimensions, represented by the equations $y = f_1(x)$, $z = f_2(x)$, the length of arc from $x_1 = a$ to $x_2 = b$ is

$$s = \int_a^b \sqrt{1 + \left(\frac{dy}{dx}\right)^2 + \left(\frac{dz}{dx}\right)^2}\, dx \tag{72}$$

Plane Area. The area bounded by the curve $y = f(x)$, the axis OX, and the ordinates at $x = a$, $x = b$ is

$$A = \int_a^b f(x)\, dx \tag{73}$$

where y has the same sign for all values of x between a and b.

In polar coordinates, the area bounded by the curve $r = f(\theta)$, and the two radii $\theta = \alpha$, $\theta = \beta$ is

$$A = {}^1\!/_2 \int_\alpha^\beta r^2\, d\theta \tag{74}$$

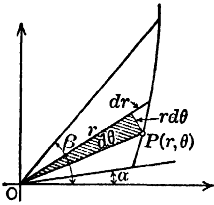

Fig. 13

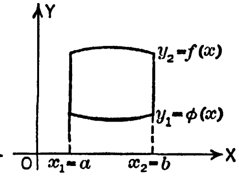

Fig. 14

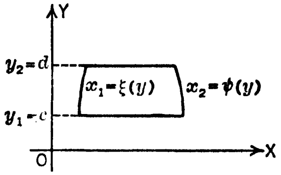

Fig. 15

In rectangular coordinates, if the area is bounded by the two curves $y_2 = f(x)$, $y_1 = \phi(x)$, and the lines $x_2 = b$, $x_1 = a$, then

$$A = \int_a^b dx \int_{\phi(x)}^{f(x)} dy \tag{75}$$

If the area is bounded by the two curves $x_2 = \psi(y)$, $x_1 = \xi(y)$, and the lines $y_2 = d$, $y_1 = c$, then

$$A = \int_c^d dy \int_{\xi(y)}^{\psi(y)} dx \tag{76}$$

If expressed in polar coordinates, the area by double integration is

$$A = \int_{\theta_1}^{\theta_2} d\theta \int_{r_1 = f_1(\theta)}^{r_2 = f_2(\theta)} r dr \quad \text{or} \quad \int_{r_1}^{r_2} r dr \int_{\theta_1 = \phi_1(r)}^{\theta_2 = \phi_2(r)} d\theta \tag{77}$$

Area of a Surface of Revolution. The area of the surface of a solid of revolution generated by revolving the curve $y = f(x)$ between $x = a$ and $x = b$:

About the x axis is $$2\pi \int_a^b y \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx \tag{78}$$

About the y axis is $$2\pi \int_c^d x \sqrt{1 + \left(\frac{dx}{dy}\right)^2}\, dy \tag{79}$$

where $c = f(a)$ and $d = f(b)$.

Volume. By triple integration:

Rectangular coordinates $$V = \int\int\int dx\, dy\, dz \tag{80}$$

Spherical coordinates $$V = \int\int\int r^2 \sin\phi\, d\theta\, d\phi\, dr \tag{81}$$

Cylindrical coordinates $$V = \int\int\int r\, dr\, d\theta\, dz \tag{82}$$

(the limits of integration to be supplied)

Volume of a Solid of Revolution. The volume of a solid of revolution generated by revolving that portion of the curve $y = f(x)$ between $x = a$ and $x = b$:

about the x axis is
$$\pi\int_a^b y^2\,dx \tag{83a}$$

about the y axis is
$$\pi\int_c^d x^2\,dy \tag{83b}$$
where $c = f(a)$ and $d = f(b)$.

Surfaces. If the equation of a surface is written in the parametric form $x = f_1(u, v)$, $y = f_2(u, v)$, $z = f_3(u, v)$ where $u = u(t)$, $v = v(t)$, the length of arc of a curve on the surface is

$$s = \int\sqrt{E\left(\frac{du}{dt}\right)^2 + 2F\frac{du}{dt}\frac{dv}{dt} + G\left(\frac{dv}{dt}\right)^2}\,dt \tag{84}$$

The area S of a portion of the surface is

$$S = \int\int\sqrt{EG - F^2}\,du\,dv \tag{85}$$

where
$$E = \left(\frac{\partial x}{\partial u}\right)^2 + \left(\frac{\partial y}{\partial u}\right)^2 + \left(\frac{\partial z}{\partial u}\right)^2$$
$$F = \frac{\partial x}{\partial u}\frac{\partial x}{\partial v} + \frac{\partial y}{\partial u}\frac{\partial y}{\partial v} + \frac{\partial z}{\partial u}\frac{\partial z}{\partial v}$$
$$G = \left(\frac{\partial x}{\partial v}\right)^2 + \left(\frac{\partial y}{\partial v}\right)^2 + \left(\frac{\partial z}{\partial v}\right)^2$$
(the limits of integration to be supplied)

If the equation of the surface is written as $x = u$, $y = v$, $z = f(u, v) = f(x, y)$,

the arc length
$$s = \int\sqrt{(1 + p^2)\left(\frac{dx}{dt}\right)^2 + 2\,p\,q\frac{dx}{dt}\frac{dy}{dt} + (1 + q^2)\left(\frac{dy}{dt}\right)^2}\,dt \tag{86}$$

the area
$$S = \int\int\sqrt{1 + p^2 + q^2}\,dx\,dy \quad \text{where } p = \frac{\partial z}{\partial x},\ q = \frac{\partial z}{\partial y} \tag{87}$$

Center of Gravity. The coordinates of the center of gravity of a mass m are

$$x = \frac{\int x\,dm}{\int dm},\quad y = \frac{\int y\,dm}{\int dm},\quad z = \frac{\int z\,dm}{\int dm} \tag{88}$$
(the limits of integration to be supplied)

Moment. The moment of a mass m

$$\left.\begin{aligned}
&\text{about the plane } YOZ, && M_{yz} = \int x\,dm;\\
&\text{about the plane } XOZ, && M_{xz} = \int y\,dm;\\
&\text{about the plane } XOY, && M_{xy} = \int z\,dm
\end{aligned}\right\} \tag{89}$$
(the limits of integration to be supplied)

Moment of Inertia. The moments of inertia, I, are

$$\left.\begin{aligned}
&\text{for a plane curve about the } X \text{ axis}, && I_x = \int y^2\,ds\\
&\text{for a plane curve about the } Y \text{ axis}, && I_y = \int x^2\,ds\\
&\text{for a plane curve about the origin}, && I_0 = \int (x^2 + y^2)\,ds
\end{aligned}\right\} \tag{90}$$

$$\left.\begin{aligned}
&\text{for a plane area about the } x \text{ axis}, && I_x = \int y^2\,dA\\
&\text{for a plane area about the } y \text{ axis}, && I_y = \int x^2\,dA\\
&\text{for a plane area about the origin}, && I_0 = \int (x^2 + y^2)\,dA
\end{aligned}\right\} \tag{91}$$

$$\left.\begin{aligned}
&\text{for a solid of mass } m \text{ about the } YOZ \text{ plane}, && I_{yz} = \int x^2\,dm\\
&\text{for a solid of mass } m \text{ about the } XOZ \text{ plane}, && I_{xz} = \int y^2\,dm\\
&\text{for a solid of mass } m \text{ about the } XOY \text{ plane}, && I_{xy} = \int z^2\,dm\\
&\text{for a solid of mass } m \text{ about the } x \text{ axis}, && I_x = I_{xz} + I_{xy}, \text{ etc.}
\end{aligned}\right\} \tag{92}$$
(the limits of integration to be supplied)

Pressure. The pressure p against an area vertical to the surface of the liquid and between the depths a and b is

$$P = \int_{y=a}^{y=b} \rho y dA \tag{93}$$

where ρ is the weight of the liquid per unit volume, y is the depth beneath the surface of the liquid of a horizontal element of area, and dA is the area of a horizontal element of area expressed in terms of y.

Center of Pressure. The depth $\bar{y}$ of the center of pressure against an area vertical to the surface of the liquid and between the depths a and b is

$$\bar{y} = \frac{\int_{y=a}^{y=b} \rho y dA}{\int_{y=a}^{y=b} \rho dA} \tag{94}$$

Work. The work W done in moving a particle from $s = a$ to $s = b$ against a force whose component expressed as a function of s in the direction of motion is $F(s)$ is

$$W = \int_{s=a}^{s=b} F(s)\, ds \tag{95}$$

DIFFERENTIAL EQUATIONS

By M. J. Fish

45. FUNDAMENTAL TYPES

Definition. Any equation containing a function of a set of variables and its derivatives is a *differential equation*. If the equation has derivatives with respect to one variable only, it is called an ***ordinary differential equation***, otherwise it is a ***partial differential equation***.

Examples.

$$\frac{d^2 y}{dx^2} + k^2 y = 0 \tag{1}$$

$$\frac{d^2 y}{dx^2} = \sqrt{1 + y^2 + \frac{dy}{dx}} \tag{2}$$

$$y \frac{\partial^2 z}{\partial x^2} + z x \frac{\partial^2 z}{\partial x \partial y} - \frac{\partial z}{\partial y} = xyz \tag{3}$$

$$y - x \frac{dy}{dx} + 3 \frac{dx}{dy} = 0 \tag{4}$$

Equations (1), (2), (4) are ordinary differential equations, and (3) is a partial differential equation.

The Order of the differential equation is the order of the highest derivative involved. Thus in (1), (2), (3), the order is two; in (4), the order is one.

The Degree of a differential equation is the exponent of the highest order appearing in the equation after it is completely rationalized and cleared of fractions. The degree of (1), (3), (4) is one; that of (2) is two.

A Solution or Integral of a differential equation is a relation between the variables which satisfies the equation identically.

A General Solution of an ordinary differential equation of the nth order is one that contains n arbitrary constants. Thus, $y = \sin x + c$, where c is an arbitrary constant, is a general solution of the equation $\frac{dy}{dx} = \cos x$.

Particular Solution. A solution which is derivable from a general solution by assigning fixed values to the arbitrary constants is called a *particular solution*. Thus, $y_1 = \sin x$, $y_2 = \sin x + 4$ are two particular solutions of the above equation.

46. ORDINARY DIFFERENTIAL EQUATIONS OF THE FIRST ORDER

Separation of Variables. A differential equation of the first order

$$f\left(x, y, \frac{dy}{dx}\right) = 0 \tag{5}$$

can be brought into the form

$$P(x, y)\,dx + Q(x, y)\,dy = 0 \tag{6}$$

For the special case where P is a function of x only and Q a function of y only,

$$P(x)\,dx + Q(y)\,dy = 0 \tag{7}$$

and the variables are separated. The solution of this is

$$\int P(x)\,dx + \int Q(y)\,dy = c \tag{8}$$

where c is an arbitrary constant.

Example. Solve, $\frac{dy}{dx} = -\frac{x}{y}$.

This can be written as $x dx + y dy = 0$ and has the solution $\int x dx + \int y dy = \frac{x^2}{2} + \frac{y^2}{2} = c$, and if $c = \frac{k}{2}$, $x^2 + y^2 = k$, which represents a set of concentric circles. There are an infinite number of solutions depending on the value for k. A definite circle of the set goes through each point (a, b) such that $a^2 + b^2 = k$.

Homogeneous Equations. A function $f(x, y)$ is said to be homogeneous of the nth degree in x and y, if, when x and y are replaced by kx and ky, respectively, the function is multiplied by k^n, regardless of the value of k, that is, $f(kx, ky) = k^n f(x, y)$. An equation

$$P(x, y)\,dx + Q(x, y)\,dy = 0 \tag{9}$$

is said to be homogeneous if the functions $P(x, y)$ and $Q(x, y)$ are homogeneous in x and y. By substituting $y = vx$, a homogeneous equation can be reduced to the form in which the variables are separable.

Example. Solve $(x^2 + y^2)dx - 2xydy = 0$.

This is of the form $P(x, y)dx + Q(x, y)dy = 0$, where P and Q are homogeneous functions of the second degree. Making the substitution $y = vx$, the equation becomes $(1 + v^2)dx - 2v(xdv + vdx) = 0$.

Separating variables $\frac{dx}{x} - \frac{2v}{1 - v^2}dv = 0$

Integrating, $\log_e x(1 - v^2) = \log_\epsilon c$, replacing $v = \frac{y}{x}$, $\log\left(1 - \frac{y^2}{x^2}\right)x = \log_e c$, and taking exponentials, $x^2 - y^2 = cx$, where c is an arbitrary constant.

The Linear Differential Equation. The differential equation

$$\frac{dy}{dx} + P(x)y = Q(x) \tag{10}$$

in which y and $\frac{dy}{dx}$ appear only in the first degree, and P and Q are functions of x, is called a *linear equation of the first order*. This has the general solution

$$y = e^{-\int P(x)dx}\left[\int Q(x)e^{\int P(x)dx}\,dx + c\right] \tag{11}$$

where c is an arbitrary constant. For the homogeneous form

$$\frac{dy}{dx} + P(x)\,y = 0 \left(\text{homogeneous with respect to } y \text{ and } \frac{dy}{dx}\right) \tag{12}$$

the general solution is $\qquad y = c_1\,e^{-\int P(x)dx} \qquad (13)$

where c_1 is an arbitrary constant.

Example. An important equation in the theory of electricity is $L\frac{di}{dt} + Ri = E$, where i is the current, L the coefficient of self-induction (a constant), R the resistance (a constant), and E the electromotive force where E may be a constant (including zero) or a function of the time. In the latter case where $E = E(t)$

$$i = e^{-(R/L)t}\left[\int \frac{E}{L}e^{(R/L)t}\,dt + c\right]$$

If $E = E_0 \sin \omega t$, then $i = e^{-(R/L)t}\,E_0\left[\int \epsilon^{(R/L)t} \sin \omega t dt + c\right]$

If E is constant and if $i = 0$ at $t = 0$, then $i = \frac{E}{R}(1 - e^{-(R/L)t})$. Note that, in this case, the method of separating variables can also be used.

The Bernoulli Equation. The equation

$$\frac{dy}{dx} + P(x)y = Q(x)y^n \tag{14}$$

in which n is a constant other than 1. By making the substitution $z = y^{1-n}$, a linear equation is obtained and the general solution is

$$y = e^{-\int P(x)dx}\left[(1-n)\int e^{(1-n)\int P(x)dx}Q(x)dx + c\right]^{\frac{1}{1-n}} \tag{15}$$

Example. Solve the equation $\frac{dy}{dx} - xy = xy^2$.

Substitute $z = y^{-1}$ and obtain $\frac{dz}{dx} + xz = -x$. The general integral is

$$z = ce^{-x^2/2} - 1 \quad \text{or} \quad y = \frac{1}{ce^{-x^2/2} - 1}.$$

Exact Differential Equation. The equation

$$P(x, y)dx + Q(x, y)dy = 0 \tag{16}$$

is called an *exact differential equation* if its left side is a complete differential

$$du = Pdx + Qdy \tag{17}$$

that is, if $\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}$.

Then,

$$\int Pdx + \int\left[Q - \frac{\partial \int Pdx}{\partial y}\right]dy = c \tag{18}$$

is an integral or solution.

Example. Solve $(x^2 - 4\,xy - y^2)dx + (y^2 - 2\,xy - 2\,x^2)\,dy = 0$.

This is an exact equation because $\frac{\partial P}{\partial y} = -4x - 2y = \frac{\partial Q}{\partial x}$.

$$\int (x^2 - 4\,xy - y^2)dx = \frac{x^3}{3} - 2\,x^2y - xy^2$$

$$\int [(y^2 - 2\,xy - 2x^2) - (-2x^2 - 2\,xy)]dy = \frac{y^3}{3}$$

The general solution is

$$\frac{x^3}{3} - 2\,x^2y - xy^2 + \frac{y^3}{3} = c$$

Integrating Factor. If the differential equation $P(x, y)dx + Q(x, y)dy = 0$ is not a complete differential, look for a factor $v(x, y)$ such that $du = v(Pdx + Qdy)$ is a complete differential. Such an *integrating factor* satisfies the equation

$$Q\frac{\partial v}{\partial x} - P\frac{\partial v}{\partial y} + \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right)v = 0 \tag{19}$$

Example. The equation $(xy^2 - y^3)dx + (1 - xy^2)dy = 0$ when multiplied by $v = \frac{1}{y^2}$ becomes $(x - y)dx + \left(\frac{1}{y^2} - x\right)dy = 0$, of which the left side $du = (x - y)dx + \left(\frac{1}{y^2} - x\right)dy$ is a complete differential since $\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}$ or $\frac{\partial}{\partial y}(x - y) = \frac{\partial}{\partial x}\left(\frac{1}{y^2} - x\right) = -1$. The integration gives $u = \frac{x^2}{2} - xy - \frac{1}{y}$. The general integral is $u = c$ or $x^2y - 2xy^2 - 2cy - 2 = 0$.

Riccati's Equation.

$$\frac{dy}{dx} + P(x)y^2 + Q(x)y + R(x) = 0 \tag{20}$$

is called *Riccati's equation.* If a particular integral y_1 is known, place $y = y_1 + \frac{1}{z}$ and obtain a linear equation for z.

47. SECOND ORDER EQUATIONS

The differential equation

$$F\left(x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}\right) = 0 \tag{21}$$

is of the *second order.* If some of these variables are missing it is possible to obtain a solution easily.

Case 1. With y and $\frac{dy}{dx}$ missing.

$$\frac{d^2y}{dx^2} = f(x) \tag{22}$$

This has the solution

$$y = \int dx \int f(x)dx + cx + c_1, \text{ or } y = x\int f(x)dx - \int x\, f(x)dx + cx + c_1 \tag{23}$$

where c and c_1 are arbitrary constants.

Case 2. With x and $\frac{dy}{dx}$ missing. $$\frac{d^2 y}{dx^2} = f(y) \tag{24}$$

Multiply both sides by $2\frac{dy}{dx}$ and obtain

$$x = \int \frac{dy}{\sqrt{c + 2\int f(y)dy}} + c_1 \tag{25}$$

as a solution, where c and c_1 are arbitrary constants.

Case 3. With x and y missing. $$\frac{d^2 y}{dx^2} = f\left(\frac{dy}{dx}\right) \tag{26}$$

Place $$\frac{dy}{dx} = p, \quad \frac{d^2 y}{dx^2} = \frac{dp}{dx}. \tag{27}$$

Then $$x = \int \frac{dp}{f(p)} + c \quad \text{and} \quad y = \int \frac{pdp}{f(p)} + c_1 \tag{28}$$

where p is obtained by elimination.

Example. Consider the differential equation of the catenary $a\frac{d^2 y}{dx^2} = \sqrt{1 + \left(\frac{dy}{dx}\right)^2}$.

Let $p = \frac{dy}{dx}$, then $a\frac{dp}{dx} = \sqrt{1 + p^2}$. By separating variables $\frac{dp}{\sqrt{1 + p^2}} = \frac{dx}{a}$ which has the solution $\sinh^{-1} p = \frac{x + c}{a}$, or $p = \frac{dy}{dx} = \sinh\frac{x + c}{a}$. Integrating this latter, $y = a\cosh\frac{x + c}{a} + c_1$.

Case 4. With y missing. $$\frac{d^2 y}{dx^2} = f\left(\frac{dy}{dx}, x\right) \tag{29}$$

Place $\frac{dy}{dx} = p$ and obtain the differential equation of the first order $\frac{dp}{dx} = f(p, x)$ which may possibly be solved for p. If so, then

$$y = \int p(x)\, dx + c \tag{30}$$

Case 5. With x missing. $$\frac{d^2 y}{dx^2} = f\left(\frac{dy}{dx}, y\right) \tag{31}$$

Place $\frac{dy}{dx} = p$ and obtain the first order equation $p\frac{dp}{dy} = f(p, y)$ which may possibly be solved for p. If so, then

$$x = \int \frac{dy}{p(y)} + c \tag{32}$$

48. LINEAR DIFFERENTIAL EQUATIONS

(1) General Theorem. The differential equation

$$\frac{d^n y}{dx^n} + P_1(x)\frac{d^{n-1} y}{dx^{n-1}} + \ldots + P_{n-1}(x)\frac{dy}{dx} + P_n(x)y = F(x) \tag{33}$$

is called the general nth order linear differential equation. If $F(x) = 0$, the equation is called *homogeneous*; otherwise it is called *complete*. If $\phi(x)$ is a solution of the complete equation and $y_1, y_2, \ldots, y_n$ are linearly independent solutions of the accompanying homogeneous equation (that is, there is no relation of the form $a_1 y_1 + a_2 y_2 + \ldots + a_n y_n = 0$ with $a_1, a_2, \ldots, a_n$ not all zero), then the general solution of (33) is

$$y = c_1 y_1 + c_2 y_2 + \ldots + c_n y_n + \phi(x) \tag{34}$$

The part $\phi(x)$ is called the *particular integral*, and the part $c_1 y_1 + \ldots + c_n y_n$ is called *the complementary function.*

(2) Homogeneous Differential Equation with Constant Coefficients.

$$\frac{d^n y}{dx^n} + a_1 \frac{d^{n-1} y}{dx^{n-1}} + \dots + a_{n-1} \frac{dy}{dx} + a_n y = 0 \tag{35}$$

is a linear homogeneous equation of the nth order with constant coefficients.

$$y_k = ce^{r_k x} \tag{36}$$

is a solution of this equation, if r_k is a root of the following algebraic equation of the nth degree:

$$r^n + a_1 r^{n-1} + \dots + a_{n-1} r + a_n = 0 \tag{37}$$

If all the n roots $r_1, r_2, \dots, r_n$ of (37) are different from each other, then

$$y = c_1 e^{r_1 x} + c_2 e^{r_2 x} + \dots + c_n e^{r_n x} \tag{38}$$

is a general integral of (35). If some of the roots are equal, for instance $r_1 = r_2 = \dots = r_k$ while $r_{k+1}, \dots, r_n$ are different from each other and from r_1, then

$$y = (c_1 + c_2 x + \dots + c_k x^{k-1})e^{r_1 x} + c_{k+1} e^{r_{k+1} x} + \dots + c_n e^{r_n x} \tag{39}$$

is the *general integral.* If $r_1 = p + iq$, $r_2 = p - iq$ are *conjugate imaginary roots* of (37), $[i = \sqrt{-1}]$, then

$$c_1 e^{r_1 x} + c_2 e^{r_2 x} = C_1 e^{px} \cos qx + C_2 e^{px} \sin qx \tag{40}$$

Example. $\frac{d^2 y}{dx^2} + 13 \frac{dy}{dx} + 40y = 0$ has the solution $y = c_1 e^{-5x} + c_2 e^{-8x}$.

$\frac{d^2 y}{dx^2} + 6 \frac{dy}{dx} + 34 y = 0$ has the solution $y = (c_1 \cos 5x + c_2 \sin 5x)e^{-3x}$.

(3) The Complete Differential Equation with Constant Coefficients.

$$\frac{d^n y}{dx^n} + a_1 \frac{d^{n-1} y}{dx^{n-1}} + \dots + a_{n-1} \frac{dy}{dx} + a_n y = F(x) \tag{41}$$

The complementary function is found as above in paragraph (2). To find the particular integral, proceed as follows. Denote

$$\frac{dy}{dx} \text{ by } D,\ \frac{d^2 y}{dx^2} \text{ by } D^2 \dots \frac{d^n y}{dx^n} \text{ by } D^n \text{ (Called the method of operators).} \tag{42}$$

Write (41) as

$$(D^n + a_1 D^{n-1} + \dots a_{n-1} D + a_n)y = F(x) \tag{43}$$

Denote (43) by $P(D)y = F(x)$ where $P(D)$ is a polynomial in D. Then there are the following rules, in which A_i, A, B are undetermined coefficients, to be determined by substituting y_p in (41) and equating coefficients of like terms:

(a) If $F(x) = x^n + a_1 x^{n-1} + \dots + a_{n-1} x + a_n$, assume the particular integral $y_p = x^n + A_1 x^{n-1} + \dots + A_{n-1} x + A_n$.

If D^m is a factor of $P(D)$, assume $y_p = (x^n + A_1 x^{n-1} + \dots + A_{n-1} x + A_n)x^m$.

(b) If $F(x) = b \sin ax$ or $b \cos ax$, assume $y_p = A \sin ax + B \cos ax$.

If $(D^2 + a^2)^m$ is a factor of $P(D)$, assume $y_p = (A \sin ax + B \cos ax)\, x^m$.

(c) If $F(x) = ce^{ax}$, assume $y_p = Ae^{ax}$. If $(D - a)^m$ is a factor of $P(D)$, assume $y_p = x^m Ae^{ax}$.

(d) If $F(x) = g(x)e^{ax}$, place $y_p = e^{ax} w$ in (41), divide out e^{ax}, and solve the equation for w as a function of x.

(e) If $F(x)$ is the sum of a number of functions, take y_p as the sum of the particular integrals corresponding to each of the functions.

Example. $\frac{d^2 y}{dx^2} + 4y = x^2 + \cos x$ can be written as $(D^2 + 4)y = x^2 + \cos x$.

Consider $(D^2 + 4)y = 0$ or $(D + i2)(D - i2)y = 0\,[i = \sqrt{-1}]$, and by the method of paragraph (2), the complementary function is $y = c_1 \cos 2x + c_2 \sin 2x$.

For a particular integral take $y_p = ax^2 + bx + c + f \sin x + g \cos x$[by (*a*), (*b*), (*e*)].

Then $\frac{d^2 y_p}{dx^2} = 2a - f \sin x - g \cos x$, and substituting in the original equation

$$\frac{d^2 y_p}{dx^2} + 4y_p = 2a - f \sin x - g \cos x + 4ax^2 + 4bx + 4c + 4f \sin x + 4g \cos x = x^2 + \cos x.$$

Equating coefficients, $a = 1/4$, $b = 0$, $c = -1/8$, $f = 0$, $g = 1/3$ and the general solution is $y = c_1 \cos 2x + c_2 \sin 2x + \frac{x^2}{4} - 1/8 + 1/3 \cos x$.

(4) Euler's Homogeneous Equation.

$$x^n \frac{d^n y}{dx^n} + ax^{n-1} \frac{d^{n-1} y}{dx^{n-1}} + \dots + a_{n-1} x \frac{dy}{dx} + a_n y = 0 \tag{44}$$

is called *Euler's homogeneous equation*. Place $x = e^t$, and since

$$\frac{dt}{dx} = \frac{1}{x}, \frac{dy}{dx} = \frac{dy}{dt}\frac{dt}{dx} = \frac{1}{x}\frac{dy}{dt}, \frac{d^2y}{dt^2} = \frac{1}{x^2}\left(\frac{d^2y}{dt^2} - \frac{dy}{dt}\right), \tag{45}$$

(44) is then replaced by a linear homogeneous differential equation with constant coefficients.

Depression of Order. If a particular integral of a linear differential equation is known, the order of the equation can be lowered. Consider the homogeneous equation

$$\frac{d^ny}{dx^n} + P_1(x)\frac{d^{n-1}y}{dx^{n-1}} + \ldots + P_{n-1}(x)\frac{dy}{dx} + P_n(x) = 0 \tag{46}$$

If y_1 is a particular integral of (46), substitute $y = y_1 z$. The coefficient of z will be found to vanish, and then by placing $\frac{dz}{dx} = u$, the equation is reduced to the $(n - 1)$st order.

Example. Given $\frac{d^2y}{dx^2} + p(x)\frac{dy}{dx} + q(x)y = 0$ and y_1, a particular integral of this equation.

Let $y = y_1 z$, then $\frac{dy}{dx} = y_1\frac{dz}{dx} + z\frac{dy_1}{dx}, \frac{d^2y}{dx^2} = y_1\frac{d^2z}{dx^2} + 2\frac{dy_1}{dx}\frac{dz}{dx} + z\frac{d^2y_1}{dx^2}$.

Substituting in the original equation

$$y_1\frac{d^2z}{dx^2} + 2\frac{dy_1}{dx}\frac{dz}{dx} + z\frac{d^2y_1}{dx^2} + p\left[y_1\frac{dz}{dx} + z\frac{dy_1}{dx}\right] + qy_1 z = 0$$

and since the coefficient of z is zero, this reduces to

$$y_1\frac{d^2z}{dx^2} + \left(2\frac{dy_1}{dx} + py_1\right)\frac{dz}{dx} = 0. \quad \text{Writing } \frac{dz}{dx} = u, \frac{du}{u} + \left(2\frac{dy_1}{dx} + py_1\right)\frac{dx}{y_1} = 0$$

By integrating, $\log_e u + \int pdx + \log_e y_1^2 = \log_c c$ or $u = \frac{c}{y_1^2}e^{-\int pdx}$.

Another integration gives z and then y; the equation admits the solution

$$y = y_1\int\frac{c}{y_1^2}e^{-\int pdx}dx + c_1.$$

Simultaneous Linear Differential Equations with Constant Coefficients. If there are two (or in general n) linear equations with constant coefficients in two (or in general n) dependent variables and one independent variable t, the symbolic or algebraic method of solution may be used. Let the equations be

$$\left.\begin{aligned}(D^n + a_1D^{n-1} + \ldots + a_n)x + (D^m + b_1D^{m-1} + \ldots + b_m)y &= R(t)\\ (D^p + c_1D^{p-1} + \ldots + c_p)x + (D^q + d_1D^{q-1} + \ldots + d_q)y &= S(t)\end{aligned}\right\} \tag{47}$$

where D denotes $\frac{d}{dt}$. The equations may be written as

$$P_1(D)x + Q_1(D)y = R, \; P_2(D)x + Q_2(D)y = S \tag{48}$$

Considering these as algebraic equations, eliminate either x or y by the method of determinants and solve the equation obtained by known methods.

Example. Solve the simultaneous equations.

$$(1)\ \frac{dx}{dt} + \frac{dy}{dt} + 2x + y = 0, \quad (2)\ \frac{dy}{dt} + 5x + 3y = 0$$

By using the symbol D these equations can be written

$$(D + 2)x + (D + 1)y = 0, \quad 5x + (D + 3)y = 0$$

Eliminating x, $(D^2 + 1)y = 0$, and from paragraph (2) this has the solution $y = c_1\cos t + c_2\sin t$. Subtituting this in (2), $x = -\frac{3c_1 + c_2}{5}\cos t + \frac{c_1 - 3c_2}{5}\sin t$.

49. PARTIAL DIFFERENTIAL EQUATIONS

First Order

Definition. If $x_1, x_2, \ldots, x_n$ are n independent variables, $z = z(x_1, x_2, \ldots, x_n)$ the dependent variable, and if

$$\frac{\partial z}{\partial x_1} = p_1, \ldots, \frac{\partial z}{\partial x_n} = p_n \tag{49}$$

then

$$F(x_1, x_2, \ldots, x_n, z, p_1, p_2, \ldots, p_n) = 0 \tag{50}$$

is a partial differential equation of the first order. An equation

$$f(x_1, x_2, \ldots, x_n, z, c_1, \ldots, c_n) = 0 \tag{51}$$

with n arbitrary constants is called a complete solution of (50) if the elimination of the constants by partial differentiation gives the differential equation (51). Thus, given the partial differential equation

$$F = z^2\left[\left(\frac{\partial z}{\partial x}\right)^2+\left(\frac{\partial z}{\partial y}\right)^2+1\right]-c^2 = 0 \tag{52}$$

Let

$$f = (x-h)^2+(y-k)^2+z^2-c^2 = 0 \tag{53}$$

be a solution, since by differentiating it with respect to x and y

$$(x-h)+z\frac{\partial z}{\partial x} = 0 \tag{54}$$

$$(y-k)+z\frac{\partial z}{\partial y} = 0 \tag{55}$$

Substituting the values of $x - h$, $y - k$ from the last two equations into f, expression F is obtained.

A singular solution is given through the elimination of $c_1, \ldots, c_n$ from the equations $f = 0$, $\frac{\partial f}{\partial c_1} = 0, \ldots, \frac{\partial f}{\partial c_n} = 0$. This differs from the particular integral in that it is not contained in the complete integral, that is, is not obtained from the complete integral by giving particular values to the constants.

Suppose that the equation $F\left(x, y, z, \frac{\partial z}{\partial x}, \frac{\partial z}{\partial y}\right) = 0$ has the complete solution $f(x, y, z, a, b) = 0$ where one of the constants $b = \phi(a)$; then $f[x, y, z, a, \phi(a)] = 0$. The general integral is found by elimination of a between $f[x, y, z, a, \phi(a)] = 0$ and $\frac{d\phi}{da} = 0$. In every equation, the general integral and the singular integral, as well as the complete integral are to be found. The complete integral is to be found first, and from it the other two are to be derived.

Linear Differential Equations.

$$P(x, y, z)p + Q(x, y, z)q = R(x, y, z) \tag{56}$$

is a partial linear differential equation. From the simultaneous ordinary equations $\frac{dx}{P} = \frac{dy}{Q} = \frac{dz}{R}$, the two independent functional solutions $u(x, y, z) = c_1$, $v(x, y, z) = c_2$ are obtained. Then $\Phi(u, v) = 0$, where Φ is an arbitrary function, is the general solution of $Pp + Qq = R$.

Examples. Given $xp + yq = q$. Consider $\frac{dx}{x} = \frac{dy}{y} = \frac{dz}{z}$, which has the solution $\log_e c_1x = \log_e c_2y = \log_e c_3z$ or $u = \frac{y}{x} = c_4$, $v = \frac{z}{x} = c_5$. Then $\Phi(u, v) = \Phi\left(\frac{y}{x}, \frac{z}{x}\right) = 0$.

Given $(ny - mz)p + (lz - nx)q = mx - ly$.

Form $\frac{dx}{ny-mz} = \frac{dy}{lz-nx} = \frac{dz}{mx-ly}$. By using the multipliers l, m, n, the equal fraction $\frac{ldx+mdy+ndz}{0}$ is obtained. Therefore $ldx + mdy + ndz = 0$, which has the solution $lx + my + nz = c_1$. In a similar manner $xdx + ydy + zdz = 0$, or $x^2 + y^2 + z^2 = c_2$. Hence the solution $\Phi(x^2 + y^2 + z^2, lx + my + nz) = 0$.

General Method of Solution. Given $F(x, y, z, p, q) = 0$, the partial differential equation to be solved. Since z depends on x and y, it follows that $dz = pdx + qdy$. Now if another relation can be found between x, y, z, p, q such as $f(x, y, z, p, q) = 0$, then p and q can be eliminated. The integral of the ordinary differential equation thus formed involving x, y, z will satisfy the given equation, $F(x, y, z, p, q) = 0$. The unknown function f must satisfy the following linear partial differential equation:

$$\frac{\partial F}{\partial p}\frac{\partial f}{\partial x}+\frac{\partial F}{\partial q}\frac{\partial f}{\partial y}+\left(p\frac{\partial F}{\partial p}+q\frac{\partial F}{\partial q}\right)\frac{\partial f}{\partial z}-\left(\frac{\partial F}{\partial x}+p\frac{\partial F}{\partial z}\right)\frac{\partial f}{\partial p}-\left(\frac{\partial F}{\partial y}+q\frac{\partial F}{\partial z}\right)\frac{\partial f}{\partial q} = 0 \tag{57}$$

which is satisfied by any of the solutions of the system

$$\frac{dx}{\frac{\partial F}{\partial p}} = \frac{dy}{\frac{\partial F}{\partial q}} = \frac{dz}{\frac{p\partial F}{\partial p}+\frac{q\partial F}{\partial q}} = \frac{-dp}{\frac{\partial F}{\partial x}+\frac{p\partial F}{\partial z}} = \frac{-dq}{\frac{\partial F}{\partial y}+\frac{q\partial F}{\partial z}} \tag{58}$$

Examples. Solve $p(q^2 + 1) + (b - z)q = 0$. Here the equations above reduce to

$$\frac{dp}{pq} = \frac{dq}{q^2} = \frac{dz}{3pq^2+p+(b-z)q} = \frac{dx}{q^2+1} = \frac{dy}{-z+b+2pq}.$$

The third fraction, by virtue of the given equation, reduces to $\frac{dz}{2pq^2}$. From the first two fractions, by integration, $q = ap$, where a is an arbitrary constant. This and the original equation determine the values of p and q, namely, $p = \frac{\sqrt{a(z-b)-1}}{a}$, $q = \sqrt{a(z-b)-1}$. Substitution of these values in $dz = pdx + qdy$ gives $dz = \left(\frac{dx}{a} + dy\right)\sqrt{a(z-b)-1}$. In this equation the variables are separable; this on integration gives $2\sqrt{a(z-b)-1} = x + ay + b$. There is no singular solution. In order to find the general integral, substitute for b some function of a and eliminate a from the complete solution. In the above work, had another pair of ratios been chosen, say $\frac{dq}{q^2} = \frac{dx}{q^2+1}$, another complete integral would have been obtained, namely,

$$(z-b)\left\{\frac{x+a}{2} - \sqrt{\left(\frac{x+a}{2}\right)^2 + 1}\right\} + y + B = 0.$$

Second Order

Definitions. A linear partial differential equation of the second order with two independent variables is of the form

$$L = Ar + 2Bs + Ct + Dp + Eq + Fz = f(x, y) \tag{59}$$

where $r = \frac{\partial^2 z}{\partial x^2}$, $s = \frac{\partial^2 z}{\partial x \partial y}$, $t = \frac{\partial^2 z}{\partial y^2}$, $p = \frac{\partial z}{\partial x}$, $q = \frac{\partial z}{\partial y}$

The coefficients $A, \ldots, F$ are real continuous functions of the real variables x and y. Let $\xi = \xi(x, y)$, $\eta = \eta(x, y)$ be two solutions of the following homogeneous partial differential equation of the first order:

$$Ap^2 + 2Bpq + Cq^2 = 0 \tag{60}$$

If $B^2 - AC = 0$, the homogeneous form of (59), $L = 0$, is called the *parabolic* type, and has the normal form

$$\frac{\partial^2 z}{\partial \xi^2} + a\frac{\partial z}{\partial \xi} + b\frac{\partial z}{\partial \eta} + cz = 0 \tag{61}$$

where a, b, c are functions of ξ and η. A familiar example is the equation of heat flow, $\frac{\partial u}{\partial t} = a^2 \frac{\partial^2 u}{\partial t^2}$ where $u = u(x, t)$ is the temperature, t is the time, a^2 is constant. If $B^2 - AC > 0$ in (60), the homogeneous form of (59) is the *hyperbolic* type which has the normal form

$$\frac{\partial^2 z}{\partial \xi \partial \eta} + a\frac{\partial z}{\partial \xi} + b\frac{\partial z}{\partial \eta} + cz = 0. \tag{62}$$

A familiar example is that of the vibrating string $\frac{\partial^2 z}{\partial t^2} = a^2 \frac{\partial^2 z}{\partial x^2}$, where z is the transverse displacement of a point on the string, with abscissa x at time t and a^2 is constant. If $B^2 - AC < 0$, the equation is of the *elliptic* type which has the normal form

$$\frac{\partial^2 z}{\partial \xi^2} + \frac{\partial^2 z}{\partial z^2} + a\frac{\partial z}{\partial \xi} + b\frac{\partial z}{\partial \eta} + cz = 0. \tag{63}$$

A familiar example is Laplace's equation $\frac{\partial^2 z}{\partial \xi^2} + \frac{\partial^2 z}{\partial \eta^2} = 0$, usually written $\nabla^2 z = 0$. The two solutions of (60) are real in the hyperbolic case and conjugate imaginary in the elliptic case. That is, in the latter case, $\xi = {}^1\!/_2\,(\alpha + i\beta)$, $\eta = {}^1\!/_2\,(\alpha - i\beta)$, where α and β are real, and $\frac{\partial^2 z}{\partial \xi \partial \eta} = \frac{1}{4}\left(\frac{\partial^2 z}{\partial \alpha^2} + \frac{\partial^2 z}{\partial \beta^2}\right)$.

As in ordinary linear equations, the complete solution consists of the complementary function and the particular integral. Also if $z = z_1$, $z = z_2, \ldots, z = z_n$ are solutions of the homogeneous equation (59), $L = 0$, then $z = c_1 z_1 + c_2 z_2 + \ldots + c_n z_n$ is again a solution.

Equations Linear in the Second Derivatives. The general type of second order equation linear in the second derivatives may be written in the form

$$Ar + Bs + Ct = V \tag{64}$$

where A, B, C, V are functions of x, y, z, p, q. From the equations

$$A\,dy^2 - B\,dx\,dy + C\,dx^2 = 0 \tag{65}$$

$$A\,dp\,dy + C\,dq\,dx - V\,dx\,dy = 0 \tag{66}$$

$$p\,dx + q\,dy = dz \tag{67}$$

it may be possible to derive either one or two relations between x, y, z, p, q called intermediary integrals and from these to deduce the general solution of (64). To obtain an intermediary integral, resolve (65), supposing the left member not a perfect square, into the two equations $dy - n_1\,dx = 0$, $dy - n_2\,dx = 0$. From the first of these and from (66), combined, if necessary, with (67), obtain the two integrals $u_1(x, y, z, p, q) = a$, $v_1(x, y, z, p, q) = b$; then $u_1 = f_1(v_1)$, where f_1 is an arbitrary function, is now an intermediary integral. In the same way, from $dy - n_2\,dx = 0$, obtain another pair of integrals $u_2 = a_1, v_2 = b_1$; then $u_2 = f_2(v_2)$ is an intermediary integral. For the final integral, if $n_1 = n_2$, the intermediary integral may be integrated. If $n_1 \neq n_2$, solve the two intermediary integrals for p and q, substitute in $pdx + q\,dy = dz$, and integrate for the complete solution.

Example. Solve

$$r^2 - a^2t = 0 \tag{64a}$$

The auxiliary equations are

$$dy - adx = 0,\ dy + adx = 0,\ \text{and}\ dp\,dy - a^2\,dx\,dq = 0 \tag{66a}$$

Hence $y + ax = c_1$, $y - ax = c_2$. Combining $y + ax = c_1$ with (66*a*), $dp + adq = 0$ is obtained, whereupon $p + aq = c_3 = f_1(y + ax)$. Combining $y - ax = c_1$ with (66*a*), $dp - adq = 0$ is obtained, whereupon $p - aq = c_4 = f_2(y - ax)$.

Solving for p and q, $p = 1/2\,[f_1(y + ax) + f_2(y - ax)]$, $q = \dfrac{1}{2a}[f_1(y + ax) - f_2(y - ax)]$. Substituting these in $pdx + qdy = dz$, $dz = \dfrac{1}{2a}[f_1(y + a)(dy + adx) - f_2(y - ax)(dy - adx)]$, which is an exact differential. Integration gives $z = \phi(y + ax) + \psi(y - ax)$. The equation $r^2 - a^2\,t = 0$ is called the equation of the vibrating string and may be solved by the method of homogeneous equation with constant coefficients.

The Homogeneous Equation with Constant Coefficients. An equation such as

$$\frac{\partial^2 z}{\partial x^2} + A_1\,\frac{\partial^2 z}{\partial x \partial y} + A_2\,\frac{\partial^2 z}{\partial y^2} = 0 \tag{68}$$

where A_1 and A_2 are constants, is an equation of this type. This equation is equivalent to

$$\left(\frac{\partial}{\partial x} - m_1\,\frac{\partial}{\partial y}\right)\left(\frac{\partial}{\partial x} - m_2\,\frac{\partial}{\partial y}\right)z = 0 \tag{69}$$

where m_1 and m_2 are roots of the auxiliary equation $X^2 + A_1X + A_2 = 0$. The general solution of (69) is

$$z = f_1(y + m_1x) + f_2(y + m_2x) \tag{70}$$

Example. Solve: $8\dfrac{\partial^2 z}{\partial x^2} + 2\dfrac{\partial^2 z}{\partial x \partial y} - 15\dfrac{\partial^2 z}{\partial y^2} = 0.$

The auxiliary equation is $8X^2 + 2X - 15 = (2X + 3)(4X - 5) = 0$. Hence $m_1 = -3/2$, $m_2 = 5/4$. The general solution is $z = f_1(2y - 3x) + f_2(4y + 5x)$.

If the auxiliary equation has multiple factors, the general solution is $z = f_1(y + m_1x) + xf_2(y + m_1x)$.

Example. Solve: $\dfrac{\partial^2 z}{\partial x^2} + 6\dfrac{\partial^2 z}{\partial x \partial y} + 9\dfrac{\partial^2 z}{\partial y^2} = 0.$

The auxiliary equation is $X^2 + 6X + 9 = (X + 3)(X + 3) = 0$. The general solution is $z = f_1(y - 3x) + x f_2(y - 3x)$.

If the coefficients in equation (68) are real, the imaginary roots of the auxiliary equation occur in conjugate pairs. Then the general solution will have the form

$$z = f(y + \alpha x + i\beta x) + g(y + \alpha x - i\beta x)[i = \sqrt{-1}].$$

Example. Solve: $\dfrac{\partial^2 z}{\partial x^2} - 2\dfrac{\partial^2 z}{\partial x \partial y} + 2\dfrac{\partial^2 z}{\partial y^2} = 0.$

The auxiliary equation is $X^2 - 2X + 2 = 0$ and $m = 1 \pm i$. The general solution is $z = f(y + x + ix) + g(y + x - ix)$, which can be written as $z = f_1(y + x + ix) + f_1(y + x - ix) + i[g_1(y + x + ix) - g_1(y + x - ix)]$, where f_1 and g_1 are any real functions. If, in particular, $f_1 = \cos u$ and $g_1 = e^u$, it can be shown that $z = 2\cos(x + y)\cosh x - 2e^{x+y}\sin x$.

Method of Particular Solutions. The solution of a partial differential equation which arises from a physical problem cannot contain any constants or functions which may be given arbitrary values. Sometimes, it is possible to find particular solutions of the partial differential equation which satisfy the boundary conditions, and by combining these particular solutions to give the solution of the physical problem. In this connection, it is sometimes possible to separate the variables. To illustrate this method, consider Laplace's equation:

$$\nabla^2 u = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0 \tag{71}$$

Let

$$u = X(x) \cdot Y(y) \tag{72}$$

where X is a function of x only, and Y a function of y only. By substitution and dividing by $X \cdot Y$, (71) becomes

$$\frac{1}{X}\frac{d^2 X}{dx^2} = -\frac{1}{Y}\frac{d^2 Y}{dy^2} \tag{73}$$

Notice that the left side does not contain y, the right side does not contain x. Since the two sides are equal, they must equal a constant, denoted by $-k^2$. Thus

$$\frac{1}{X}\frac{d^2X}{dx^2} = -k^2,\ \frac{1}{Y}\frac{d^2 Y}{dy^2} = k^2 \tag{73a}$$

the solutions of which are respectively

$$X = c_1 \cos k x + c_2 \sin kx,\ Y = c_3\, e^{ky} + c_4\, e^{-ky} \tag{74}$$

(see Ordinary Homogeneous Differential Equation with Constant Coefficients, second order). Hence, from (72),

$$\begin{aligned} u &= (c_1 \cos kx + c_2 \sin kx)(c_3\, e^{ky} + c_4\, e^{-ky}) \\ &= e^{ky}(A \cos kx + B \sin kx) + e^{-ky}(D \cos kx + E \sin kx) \end{aligned} \tag{75}$$

where A, B, D, E are arbitrary constants. Since (71) is linear, the sum of any number of solutions is again a solution. An infinite number of solutions may be taken provided the series converges in such a way that it may be differentiated term by term. Then, if this condition is fulfilled,

$$u = \sum_{n=0}^{\infty} [e^{ky}(A_n \cos kx + B_n \sin kx) + e^{-ky}(D_n \cos kx + E_n \sin kx)] \tag{76}$$

is a solution of (71). By development in a Fourier series, the constants can be determined so as to satisfy the given boundary conditions.

The equation of Laplace plays an important rôle in physics. Functions which satisfy it are called *harmonic.* (71) in polar coordinates becomes,

$$\frac{\partial^2 u}{\partial r^2} + \frac{1}{r^2}\frac{\partial^2 u}{\partial \theta^2} + \frac{1}{r}\frac{\partial u}{\partial r} = 0 \tag{77}$$

In three variables, Laplace's equation in cartesian coordinates is

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0 \tag{78}$$

In cylindrical coordinates,

$$\frac{\partial^2 u}{\partial r^2} + \frac{1}{r}\frac{\partial u}{\partial r} + \frac{1}{r^2}\frac{\partial^2 u}{\partial \theta^2} + \frac{\partial^2 u}{\partial z^2} = 0 \tag{79}$$

In spherical coordinates,

$$r^2 \frac{\partial^2 u}{\partial r^2} + 2r \frac{\partial u}{\partial r} + \frac{\partial^2 u}{\partial \phi^2} + \cot \phi \frac{\partial u}{\partial \phi} + \csc^2 \phi \frac{\partial^2 u}{\partial \theta^2} = 0 \tag{80}$$

SOLUTION OF LINEAR CONSTANT-COEFFICIENT INTEGRO-DIFFERENTIAL EQUATIONS BY THE LAPLACIAN TRANSFORMATION (HEAVISIDE OPERATIONAL CALCULUS)

By J. L. Barnes

50. METHOD OF TRANSFORMATION

The method for solving equations mentioned in the heading of this section is essentially the same as the Heaviside operational calculus, and is based on the Laplacian (and in special cases, Fourier) transformation.

The chief advantage of this method over others is that it provides a simpler way for solving linear constant-coefficient differential equations as well as integral and integro-differential equations of a particular (convolution) type. One of the reasons for this simplicity is that the method is straightforward.

The following treatment will be restricted to a statement of the more important properties and steps of procedure with an illustration of their use. For the purpose of simplifying this presentation the conditions under which the steps may be validly applied will be omitted. Hence the correctness of a final result obtained by the procedure should be checked in each case by showing that it satisfies the given equation and conditions.

1. Direct Laplacian transformation. Let t denote a real variable, s a complex variable (see p. 2–112), $f(t)$ a real function of t which equals zero for $t < 0$, $F(s)$ a function of s, and e the base of the natural logarithms. If

$$\int_0^\infty e^{-st} f(t)\, dt = F(s) \tag{1}$$

then $F(s)$ is called the *direct Laplacian transform* of $f(t)$, and in simpler notation

$$\mathcal{L}[f(t)] = F(s) \tag{2}$$

2. Inverse Laplacian transformation. Under certain conditions the direct transformation can be inverted, giving

$$\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty} e^{ts} F(s)\, ds = f(t) \tag{3}$$

in which c is a real constant chosen so that the path of integration lies to the right of all the singularities of $F(s)$. If this relation holds then $f(t)$ is called the *inverse Laplacian transform* of $F(s)$. In simpler notation the transformation is written

$$\mathcal{L}^{-1}[F(s)] = f(t) \tag{4}$$

3. Transformation of nth derivative. If $\mathcal{L}[f(t)] = F(s)$, then

$$\mathcal{L}\left[\frac{d^n f(t)}{d t^n}\right] = s^n F(s) - \sum_{k=0}^{n-1} f^{(k)}(0)\cdot s^{n-1-k} \tag{5}$$

where $f^{(2)}(0)$ means $\dfrac{d^2 f(t)}{d t^2}$ evaluated at $t = 0$, and $f^{(0)}(0)$ means $f(0)$, and $n = 1, 2, 3, \ldots.$

4. Transformation of nth integral. If $\mathcal{L}[f(t)] = F(s)$, then

$$\mathcal{L}\left[\int\int\cdots\int f(t)\, dt\right] = s^{-n} F(s) + \sum_{k=-1}^{-n} f^{(k)}(0)\cdot s^{-n-1-k} \tag{6}$$

where $f^{(-2)}(0)$ means $\int\int f(t)\, dt$ evaluated at $t = 0$, and $n = 1, 2, 3, \ldots.$

5. Inverse transformation of product. If

$$\mathcal{L}^{-1}[F_1(s)] = f_1(t), \quad \mathcal{L}^{-1}[F_2(s)] = f_2(t) \tag{7}$$

then

$$\mathcal{L}^{-1}[F_1(s)\cdot F_2(s)] = \int_0^t f_1(t-\lambda)\cdot f_2(\lambda)\, d\lambda \tag{8}$$

6. Linear transformations $\mathcal{L}$ and $\mathcal{L}^{-1}$. Let k_1, k_2 denote real constants. Then

$$\mathcal{L}[k_1 f_1(t) + k_2 f_2(t)] = k_1 \mathcal{L}[f_1(t)] + k_2 \mathcal{L}[f_2(t)] \tag{9}$$

and

$$\mathcal{L}^{-1}[k_1 F_1(s) + k_2 F_2(s)] = k_1 \mathcal{L}^{-1}[F_1(s)] + k_2 \mathcal{L}^{-1}[F_2(s)] \tag{10}$$

51. PROCEDURE

To illustrate the application of the rules of procedure the following simple initial-value problem will be solved.

$$k_1 \frac{dy(t)}{dt} + k_2 y(t) + k_3 \int y(t)\, dt = u(t)$$

$$y(0) \neq 0, \; y^{(-1)}(0) \neq 0$$

where $u(t) = 0$ for $t < 0$, and 1 for $0 < t$, and k_1, k_2, k_3 are real constants. Assume that $y(t)$ has a Laplacian transform $Y(s)$, that is, $\mathcal{L}[y(t)] = Y(s)$.

Step A. Find the Laplacian transform of the equation to be solved and express it in terms of the transform of the unknown function.

Thus,

$$\mathcal{L}\left[k_1 \frac{dy(t)}{dt} + k_2 y(t) + k_3 \int y(t)\, dt\right] = \mathcal{L}[u(t)]$$

By **6** this becomes

$$k_1 \mathcal{L}\left[\frac{dy(t)}{dt}\right] + k_2 \mathcal{L}[y(t)] + k_3 \mathcal{L}\left[\int y(t) dt\right] = \mathcal{L}[u(t)]$$

By 3 and 4 and the given initial conditions of the problem the equation becomes

$$k_1[s\,Y(s) - y(0)] + k_2\,Y(s) + k_3[s^{-1}\,Y(s) + y^{(-1)}(0)\cdot s^{-1}] = \mathcal{L}[u(t)].$$

Step B. Solve the resulting equation for the transform of the unknown function.

Thus,
$$Y(s) = \frac{\mathcal{L}[u(t)] + k_1\,y(0) - y^{(-1)}(0)\cdot s^{-1}}{k_1\,s + k_2 + k_3\,s^{-1}}$$

Step C. Evaluate the direct transform of the given function (right member) in the original equation.

Note. One way to carry out step **C** is to find the transform from a table of transforms. An extensive table of direct and inverse Fourier transforms which in most cases can be interpreted directly as Laplacian transforms has been compiled by G. A. Campbell and R. M. Foster (Bell Telephone System Monograph B–584). In the present example $\mathcal{L}[u(t)] = \frac{1}{s}$, so

$$Y(s) = \frac{k_1\,y(0)\cdot s - y^{(-1)}(0) + 1}{k_1\,s^2 + k_2\,s + k_3}.$$

Step D. Obtain the solution of the problem by evaluating the inverse Laplacian transform of the function obtained by the preceding steps.

Note. One way to carry out step **D** is to find the inverse transform from a table such as that mentioned above. To employ the table, the denominator of the fraction should be factored.

$$y(t) = \mathcal{L}^{-1}[Y(s)] = \mathcal{L}^{-1}\left[\frac{k_1\,y(0)\cdot s - y^{(-1)}(0) + 1}{k_1\,s^2 + k_2\,s + k_3}\right] =$$
$$= \mathcal{L}^{-1}\left[\frac{k_1\,y(0)\cdot s - y^{(-1)}(0) + 1}{k_1\,(s + K_1)(s + K_2)}\right]$$

in which
$$K_1 \equiv \frac{k_2}{2k_1} - \frac{1}{2k_1}\,(k_2^2 - 4\,k_1\,k_3)^{1/2},$$
$$K_2 \equiv \frac{k_2}{2k_1} + \frac{1}{2k_1}\,(k_2^2 - 4\,k_1\,k_3)^{1/2}$$

To find the result it is necessary to distinguish between two cases.

Case 1: If $K_1 \neq K_2$,

$$y(t) = \{[k_1\,y(0)\,K_1 + y^{(-1)}(0) - 1]\,e^{-K_1 t} -$$
$$-[k_1\,y(0)\,K_2 + y^{(-1)}(0) - 1]\,e^{-K_2 t}\}/[k_1\,(K_1 - K_2)]$$

for $0 < t$, and $= 0$ for $t < 0$.

Case 2: If $K_1 = K_2 = K$, then $K = \frac{k_2}{2k_1}$, and

$$y(t) = \mathcal{L}^{-1}\left[\frac{k_1\,y(0)\cdot s - y^{(-1)}(0) + 1}{k_1\,(s + K)^2}\right]$$

From the table,

$$y(t) = \{k_1\,y(0)\,e^{-Kt} - [y^{(-1)}(0) - 1 + k_1\,y(0)\,K]\,te^{-Kt}\}/k_1,$$

for $0 < t$, and $= 0$ for $t < 0$.

To save space it will not be shown here that the solutions obtained satisfy the original equation and initial conditions.

The use of rule **C** can be avoided by using rules **E**, **F**, and **G** in place of rules **C** and **D** in the following way.

Step E. Factor the transform of the unknown function obtained by rule **B**, and evaluate the inverse Laplacian transform of each factor.

Note. The inverse transform of a rational fraction can be found only if the degree of the numerator is one or more less than the degree of the denominator.

Thus,
$$Y(s) = \frac{k_1\,y(0)\cdot s - y^{(-1)}(0)}{k_1\,s^2 + k_2\,s + k_3} + \frac{s\,\mathcal{L}[u(t)]}{k_1\,s^2 + k_2\,s + k_3}.$$

$$\text{Let } y_1(t) \equiv \mathcal{L}^{-1}\left[\frac{k_1\,y(0)\cdot s - y^{(-1)}(0)}{k_1(s + K_1)(s + K_2)}\right] = \{[k_1\,y(0)\,K_1 + y^{(-1)}(0)]\,e^{-K_1 t} -$$
$$-[k_1\,y(0)\,K_2 + y^{(-1)}(0)]e^{-K_2 t}\}/[k_1\,(K_1 - K_2)], \text{ for}$$

$0 < t$, and $= 0$ for $t < 0$. Also

$$\mathcal{L}^{-1}\left[\frac{s}{k_1(s + K_1)(s + K_2)}\right] = (K_1\,e^{-K_1 t} - K_2\,e^{-K_2 t})/[k_1(K_1 - K_2)]$$

for $0 < t$, and $= 0$ for $t < 0$. Finally, $\mathcal{L}^{-1}\{\mathcal{L}[u(t)]\} = u(t)$.

Step F. Use **5** to find the inverse transform of the product.
Thus, by **6** and step **F**,

$$y(t) = y_1(t) + [k_1(K_1 - K_2)]^{-1}\int_0^t [K_1\, e^{-k_1(t-\lambda)} - K_2\, e^{-K_2(t-\lambda)}]\, u(\lambda)\, d\lambda.$$

Step G. Evaluate the (convolution) integral arising from step **F**. Thus,

$$y(t) = y_1(t) + [k_1(K_1 - K_2)]^{-1} (e^{-K_2 t} - e^{-K_1 t}),\ \text{for } 0 < t, \text{ and } = 0 \text{ for } t < 0.$$

It may be easily seen that for the particular problem treated above it is much simpler to use steps **C** and **D** than steps **E**, **F**, and **G**. However, for a more complicated right member of the original equation it could happen that step **G** would be easier to carry out than step **C**, in which case the second method (**A**, **B**, **E**, **F**, **G**) should be used rather than the first (**A**, **B**, **C**, **D**).

One physical representation of the initial-value problem which we have used for illustration is the problem of finding the current response of a series electrical circuit containing constant lumped inductance, resistance, and capacitance to an applied electromotive force $u(t)$, with an initial current in the inductance and an initial charge on the condenser.

The particular advantages of this transform method are not brought out well by the simple problem used for illustration of the procedure, but appear more clearly when systems of higher order ordinary integro-differential equations or partial differential equations are treated. The complete method (of which only a part has been given above) is not restricted in its field of application to linear equations with constant coefficients, but the solution of this type of equation is most simplified.

Books and papers on the subject should be consulted for alternative methods of evaluating the direct and inverse transforms and for further properties and applications of the Laplacian transformation.

FUNCTIONS OF COMPLEX VARIABLES

By M. J. Fish

52. COMPLEX NUMBERS

Complex Numbers. A complex number or vector is the combination of two ordinary real numbers a, b in the ordered pair $(a, b) = a + i\,b$. where $i^2 = -1$. Real and imaginary numbers are special cases of complex numbers obtained by placing $(a, 0) = a$, $(0, b) = ib$.

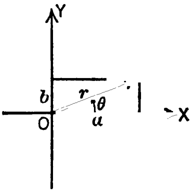

FIG. 1

1. If $a + ib = 0$, then $a = 0$, $b = 0$.
2. If $a + ib = c + id$, then $a = c$, $b = d$.
3. $a + ib$ and $a - ib$ are conjugate complex numbers.
4. $(a + ib)(a - ib) = a^2 + b^2$.
5. $\dfrac{a + ib}{c + id} = \dfrac{(a + ib)(c - id)}{(c + id)(c - id)} = \dfrac{ac + bd}{c^2 + d^2} + i\dfrac{bc - ad}{c^2 + d^2}$.
6. $a + ib = r(\cos\theta + i\sin\theta) = e^{i\theta}$;
   $a - ib = r(\cos\theta - i\sin\theta) = e^{-i\theta}$,

where $r = +\sqrt{a^2 + b^2}$, $\sin\theta = \dfrac{b}{r}$, $\cos\theta = \dfrac{a}{r}$, r is called the *absolute value* (the *modulus*), and θ, the *argument*.

7. $(\cos\theta \pm i\sin\theta)^n = e^{\pm in\theta} = \cos n\,\theta \pm i\sin n\theta$ (n arbitrary).
8. $\sqrt[n]{a + ib} = |\sqrt[n]{r}|\left(\cos\dfrac{\theta + 2k\pi}{n} + i\sin\dfrac{\theta + 2k\pi}{n}\right) = |\sqrt[n]{r}|\, e^{i(\theta + 2k\pi)/n}$

where k is an integer; for $k = 0, 1, 2 \ldots, n - 1$, all the different values of the root are obtained.

Addition of Two Complex Numbers.

$$(a + ib) + (c + id) = (a + c) + i\,(b + d) \qquad (1)$$

(See addition of vectors.)

Multiplication of Two Complex Numbers. To multiply z_1 and z_2, multiply their moduli and add their arguments. This can best be accomplished by use of the exponential form;

$$z_1 = r_1\, e^{i\theta_1},\ z_2 = r_2\, e^{i\theta_2},\ z_1 z_2 = r_1 r_2\, e^{i(\theta_1+\theta_2)} \qquad (2)$$

To divide $\dfrac{z_1}{z_2}$, divide the moduli and subtract their arguments;

$$\frac{z_1}{z_2} = \frac{r_1}{r_2}\, e^{i(\theta_1-\theta_2)} \qquad (3)$$

53. COMPLEX VARIABLES

Analytic Functions of Complex Variables. A function $w = f(z)$, $z = x + iy$, which has at each point of a region in the z plane a derivative

$$\lim_{h \to 0} \frac{f(z+h) - f(z)}{h} = f'(z) \tag{4}$$

where $f'(z)$ has the same value independent of the manner of approach of $z + h$ to z, is called *analytic* in this region and may be developed in a convergent power series. By separation of $w = u(x,y) + i\,v(x,y)$ into its real and imaginary parts and allowing $z + h$ to approach z first along the real axis, then along the imaginary axis,

$$f'(z) = \frac{\partial u}{\partial x} + i\frac{\partial v}{\partial x} = -i\frac{\partial u}{\partial y} + \frac{\partial v}{\partial y} \tag{5}$$

Thus the Cauchy-Riemann differential equations are obtained:

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y};\ \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x} \tag{6}$$

If these four partial derivatives exist and are continuous at all points of the region, the Cauchy-Riemann equations are necessary and sufficient conditions for a function to be analytic in the region. The Cauchy-Riemann equations satisfy Laplace's equation:

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = 0, \text{ for } \phi = u \text{ and } v \tag{7}$$

Examples of analytic functions are: z^2, $\frac{1}{z}$, e^x, $\sin x$ . . . . The function $w = x - iy$ has a different limit for the differential quotient by an approach along the real axis from that along the imaginary axis and is therefore not analytic. This can be found from the nonexistence of the Cauchy-Riemann equations.

Conformal Mapping. Consider the equation $w = f(z)$. To every point in the z plane corresponds a point in the w plane, and there is a mapping of the corresponding points. If $w = f(z)$ is an analytic function, then at the points where $f'(z) \neq 0$, two curves in the w plane cut each other at the same angle as two corresponding curves in the z plane. In addition, each line element in the z plane has the same ratio of length to each corresponding line element in the w plane. This ratio of length is $f'(z) = \frac{dw}{dz}$. Such a mapping is called *conformal*. Examples. (1) $w = z + c$, where c is complex, represents a displacement of the z plane parallel to and with the magnitude of the vector c.

(2) $w = az + b$ ($a \neq 0$; $a \neq 1$), a and b complex, represents a parallel displacement of amount b, a rotation equal to the argument of a, and a stretching or contraction in the ratio $1/a$. The point $z = \frac{b}{1-a}$ remains fixed.

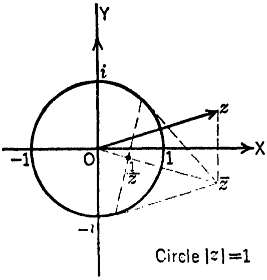

FIG. 2

(3) $w = 1/z$ is the inversion transformation. The point $z = 0$ transforms into $w = \infty$. The inside of the unit circle, $|z| = 1$ (Fig. 2) becomes, in the w plane, the outside of the unit circle $|w| = 1$, with the circle taken in the opposite direction. Circles and straight lines in the z plane which go through the point $z = 0$ become straight lines in the w plane. In particular, circles in the z plane which are tangent at $z = 0$ become parallel lines in the w plane.

VECTOR ANALYSIS

By M. J. Fish

54. SUM AND PRODUCT OF VECTORS

A Vector is a directed segment of a straight line. Quantities in physics which have magnitude and direction, such as force, velocity, acceleration, can be represented by means of vectors. A *scalar* is a quantity which has magnitude but no direction. For example, mass, density, temperature are scalar quantities

Two vectors A and B are equal if they have the same length and direction. A vector may be displaced parallel to itself in space, provided it retains the same length and direction. A vector having the same length but direction opposite to that of A is the negative of the latter and is written $-A$. If A is a vector of length a, then $|A| = a$. The vector parallel to A but with length equal to the reciprocal of the length of A is written $A^{-1} = 1/A$. The unit vector $\frac{A}{|A|}$ $(A \neq 0)$ is a vector having the direction of A and length 1.

The Sum of two vectors A and B is $A + B = B + A$ (Fig. 1). Similarly, the sum of three or more vectors can be found by using $A + B$ as one side and continuing as above.

The sum of A and $-B$ is $A - B$ (Fig. 1), the difference of two vectors. If p is a scalar and A a vector, then $pA = Ap$ represents a vector p times as long as A with the same direction as A if p is positive and opposite if p is negative. If p, q are scalars, then

$$(p + q)\,A = pA + qA;\; p(A + B) = pA + pB \tag{1}$$

In operations with vectors, the following algebraic laws are valid:

$$A + B = B + A, \text{ commutative.} \tag{2}$$

$$A + (B + C) = (A + B) + C, \text{ associative.} \tag{3}$$

$$p(A + B) = pA + pB, \text{ distributive.} \tag{4}$$

$$|A + B| \leqq |A| + |B|$$

where the equality sign holds only for A parallel to B.

Rectangular Coordinates. Fig. 2 shows a right-handed system of coordinates; that is, a right-handed rotation of 90° about OZ carries OX into OY. Let i, j, k be unit vectors with the directions OX, OY, OZ, respectively. The point $P(x, y, z)$ is the terminus of a vector $OP = R$ such that

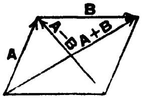

Fig. 1

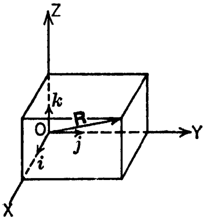

Fig. 2

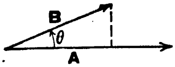

Fig. 3

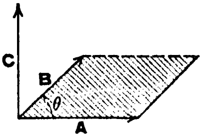

Fig. 4

$$R = ix + jy + kz \tag{5}$$

where the three vectors on the right are called the components of R. Given two vectors $A = ia + jb + kc$ and $A_1 = ia_1 + jb_1 + kc_1$, then

$$A + A_1 = i(a + a_1) + j(b + b_1) + k(c + c_1) \tag{6}$$

Scalar Product. The scalar product of two vectors is sometimes called the inner product or the dot product. It is

$$A \cdot B = |A|\,|B| \cos\theta \quad \text{(Fig. 3)} \tag{7}$$

The following algebraic rules are valid:

$A \cdot B = B \cdot A$

$A \cdot (B + C) = A \cdot B + A \cdot C$

If $A \cdot B = 0$, then either $A = 0$, $B = 0$, or A is perpendicular to B.

$A \cdot A = A^2 = |A|^2$

$i \cdot i = j \cdot j = k \cdot k = 1$

$i \cdot j = j \cdot k = k \cdot i = 0$

If $A = ia_1 + ja_2 + ka_3$ and $B = ib_1 + jb_2 + kb_3$, then $A \cdot B = a_1 b_1 + a_2 b_2 + a_3 b_3$.

Vector Product. The vector product of two vectors is sometimes called the outer product or the cross-product. It is $A \times B = C$, where C is perpendicular to the plane of A and B with the magnitude $|C| = |A|\,|B| \sin\theta$ (the area of the parallelogram made by A and B, Fig. 4) and so directed that a right-hand rotation of less than 180° carries A into B. The following algebraic rules are valid:

$A \times B = -B \times A$

$A \times (B + C) = A \times B + A \times C$

$(B + C) \times A = B \times A + C \times A$

If $A \times B = 0$, then either $A = 0$, $B = 0$, or A is parallel to B.

$$i \times i = j \times j = k \times k = 0$$
$$i \times j = k = -j \times i$$
$$j \times k = i = -k \times j$$
$$k \times i = j = -i \times k$$

If $A = ia_1 + ja_2 + ka_3$ and $B = ib_1 + jb_2 + kb_3$, then $A \times B = \begin{vmatrix} i & j & k \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix}$.

If
$$A = ia_1 + ja_2 + ka_3$$
$$B = ib_1 + jb_2 + kb_3$$
$$C = ic_1 + jc_2 + kc_3$$
then the triple scalar product

$$A \cdot (B \times C) = (A \times B) \cdot C = B \cdot (C \times A) = (A\ B\ C) = \begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix}$$

and is equal to the volume of a parallelepiped whose three determining edges are A, B, C.

The product

$$(A \times B) \times C = (A \cdot C)B - (B \cdot C)A = -C \times (A \times B)$$
$$(A \times B) \cdot (C \times D) = (A \cdot C)(B \cdot D) - (A \cdot D)(B \cdot C)$$

55. DIFFERENTIATION AND INTEGRATION OF VECTORS

Differentiation. A vector whose magnitude and direction depend on one or more scalar variables is called a *variable vector.* Continuity and differentiability are defined exactly as for scalar variables. The derivative is

$$\frac{dF}{dt} = F'(t) = \lim_{\Delta t \to 0} \frac{F(t + \Delta t) - F(t)}{\Delta t} = \lim_{\Delta t \to 0} \frac{\Delta F}{\Delta t} \quad \text{(Fig. 5)} \tag{8}$$

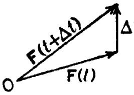

FIG. 5

If the length of F remains unaltered, then $F \cdot dF = 0$. If the direction of F remains unaltered, then $F \times dF = 0$.

The following rules are valid:

$$d(A + B) = dA + dB$$
$$d(A \cdot B) = A \cdot dB + B \cdot dA$$
$$d(A \times B) = dA \times B + A \times dB = A \times dB - B \times dA$$
$$d(A \cdot B \cdot C) = A \cdot B \cdot dC + B \cdot C \cdot dA + C \cdot A \cdot dB$$

The Differential Operators.

Let
$$\nabla = \text{"}del\text{"} = i\frac{\partial}{\partial x} + j\frac{\partial}{\partial y} + k\frac{\partial}{\partial z} \tag{9}$$

If V is a scalar function,

then
$$\nabla V = grad\ V = i\frac{\partial V}{\partial x} + j\frac{\partial V}{\partial y} + k\frac{\partial V}{\partial z} \tag{10}$$

If A is a vector with components A_x, A_y, A_z,

then
$$\nabla \cdot A = div\ A = \frac{\partial A_x}{\partial x} + \frac{\partial A_y}{\partial y} + \frac{\partial A_z}{\partial z} \tag{11}$$

$$\nabla \times A = curl\ A = rot\ A = \begin{vmatrix} i & j & k \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ A_x & A_y & A_z \end{vmatrix} \tag{12}$$

$$\nabla^2 = Laplacian = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \tag{13}$$

Formulas for Differentiation. Let U and V be scalar functions and A and B be vector functions of x, y, z. Then:

$$\nabla(U + V) = \nabla U + \nabla V;\quad \nabla \cdot (A + B) = \nabla \cdot A + \nabla \cdot B;\quad \nabla \times (A + B) = \nabla \times A + \nabla \times B$$
$$\nabla(UV) = V\nabla U + U\nabla V;\quad \nabla \cdot (UA) = U\nabla \cdot A + A \cdot \nabla U;\quad \nabla \times (UA) = \nabla U \times A + U\nabla \times A$$
$$\nabla \cdot (A \times B) = B \cdot \nabla \times A - A \cdot \nabla \times B$$
$$\nabla(A \cdot B) = A \cdot \nabla B + B \cdot \nabla A + A \times (\nabla \times B) + B \times (\nabla \times A)$$
$$\nabla \times (A \times B) = B \cdot \nabla A - A \cdot \nabla B + A(\nabla \cdot B) - B(\nabla \cdot A)$$

$\nabla\times(\nabla\times A) = \nabla(\nabla\cdot A) - \nabla^2 A$

$\nabla\cdot(\nabla\times A) = 0$

$\nabla\times(\nabla U) = 0$

If $R = ix + jy + kz$ (Fig. 2), then

$$\nabla\cdot R = 3;\ \nabla\times R = 0;\ A\cdot\nabla R = A;\ \nabla\cdot\frac{1}{|R|} = -\frac{R}{|R|^3};\ \nabla^2\frac{1}{|R|} = 0.$$

Integration. The line integral of a vector F along a curve AB denotes the integral of the tangential component of the vector along the curve; thus

$$\int_A^B F\cdot dR = \int_A^B |F_c|\, ds \text{ (Fig. 6)} \tag{14}$$

where $dR = idx + jdy + kdz$.

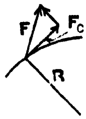

FIG. 6

If $F = \nabla U$ is the gradient of a single-valued continuous function $U(x,y,z)$ the line integral of F depends only on the end points. Conversely, if $F(x, y, z)$ is continuous and $\int_C F\cdot dR = 0$ for any closed path C in a three-dimensional region, there is a function $U(x, y, z)$ such that $F = \nabla U$.

56. THEOREMS AND FORMULAS

Let n be the vector of unit length perpendicular to a surface at a point P and extending on the positive side (the outward normal); dS, the element of surface, and dv, the element of volume.

The Divergence (Gauss) Theorem. Consider any closed surface S, lying in a vector field F, then

$$\iint_S F\cdot n\, dS = \iiint_v \nabla\cdot F\, dv \tag{15}$$

where $\nabla\cdot F$ is continuous and by a vector field is meant that to every point of the region there is a corresponding value of the vector.

Stokes' Theorem.

$$\iint_S \nabla\times F\cdot n\, dS = \int_C F\cdot dR \tag{16}$$

where C is the curve bounding S.

Green's Theorem.

$$\iint_S n\cdot U\nabla V\, dS = \iiint_v U\nabla^2 V\, dv + \iiint_v (\nabla U\cdot\nabla V)\, dv \tag{17}$$

$$\iint_S n\cdot(U\nabla V - V\nabla U)\, dS = \iiint_v (U\nabla^2 V - V\nabla^2 U)\, dv \tag{18}$$

Cylindrical Coordinates.

$$x = r\cos\theta,\ y = r\sin\theta,\ z = z$$

The element of volume $dv = r\,dr\,d\theta\,dz$. The unit vectors u_r, u_θ, u_z are perpendicular to each other.

$$\text{Grad } V = \nabla V = \frac{\partial V}{\partial r}u_r + \frac{1}{r}\frac{\partial V}{\partial\theta}u_\theta + \frac{\partial V}{\partial z}u_z \tag{19}$$

$$\text{Div } F = \nabla\cdot F = \frac{1}{r}\frac{\partial}{\partial r}(rF_r) + \frac{1}{r}\frac{\partial}{\partial\theta}(F_\theta) + \frac{\partial}{\partial z}(F_z) \tag{20}$$

$$\text{Curl } F = \nabla\times F = \begin{vmatrix} \dfrac{u_r}{r} & u_\theta & \dfrac{u_z}{r} \\ \dfrac{\partial}{\partial r} & \dfrac{\partial}{\partial\theta} & \dfrac{\partial}{\partial z} \\ F_r & rF_\theta & F_z \end{vmatrix} \tag{21}$$

$$\nabla^2 V = \frac{1}{r}\frac{\partial V}{\partial r} + \frac{\partial^2 V}{\partial r^2} + \frac{1}{r^2}\frac{\partial^2 V}{\partial\theta^2} + \frac{\partial^2 V}{\partial z^2} \tag{22}$$

Spherical Coordinates.

$$x = r\cos\theta\sin\phi,\ y = r\sin\theta\sin\phi,\ z = r\cos\phi$$

The unit vectors u_r, u_ϕ, u_θ are perpendicular to each other.

$$\text{Grad } V = \nabla V = \frac{\partial V}{\partial r}u_r + \frac{1}{r\sin\phi}\frac{\partial V}{\partial\theta}u_\theta + \frac{1}{r}\frac{\partial V}{\partial\phi}u_\phi \qquad (2$$

$$\text{Div } F = \nabla \cdot F = \frac{1}{r^2}\frac{\partial}{\partial r}(r^2 F_r) + \frac{1}{r \sin\phi}\frac{\partial F_\theta}{\partial \theta} + \frac{1}{r \sin\phi}\frac{\partial}{\partial \phi}(\sin\phi\, F_\phi) \tag{24}$$

$$\text{Curl } F = \nabla \times F = \begin{vmatrix} \frac{u_r}{r^2 \sin\phi} & \frac{u_\phi}{r \sin\phi} & \frac{u_\theta}{r} \\ \frac{\partial}{\partial r} & \frac{\partial}{\partial \phi} & \frac{\partial}{\partial \theta} \\ F_r & rF_\phi & r \sin\phi\, F_\theta \end{vmatrix} \tag{25}$$

$$\nabla^2 V = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2 \frac{\partial V}{\partial r}\right) + \frac{1}{r^2 \sin^2\phi}\frac{\partial^2 V}{\partial \theta^2} + \frac{1}{r^2 \sin\phi}\frac{\partial}{\partial \phi}\left(\sin\phi \frac{\partial V}{\partial \phi}\right) \tag{26}$$

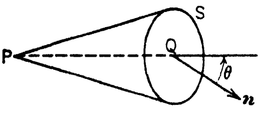

FIG. 7

Solid Angle. The lines joining the point P to points of a surface S generate a solid angle. If a is the area intercepted by these lines on a sphere of center P with radius r, then

$$\omega = \frac{a}{r^2} \tag{27}$$

is the measure of the solid angle. If S is a surface such that it does not pass through P, $\cos\theta$ is nowhere zero, and n is everywhere continuous on the surface, then

$$\omega = \int_s \frac{R \cdot n\, da}{r^3} \tag{28}$$

where $R = PQ$. If S forms the complete boundary of a three-dimensional region, the total solid angle subtended by S at P is zero if P lies outside the region, and 4π if P lies inside the region.

ALIGNMENT CHARTS—NOMOGRAMS

By J. G. Brainerd

57. DEFINITION

An Alignment Chart is a group of curves so placed, and with scales so arranged, that there exists a simple method of determining points on the curves which correspond to a set of simultaneous values of the variables in a given equation for which the chart has been constructed. The term *nomogram* is frequently used in place of *alignment chart.*

Use. The most extensive use of alignment charts is for the purpose of eliminating computations which (1) involve equations containing three or four variables, and (2) must be made frequently enough to warrant construction of a chart.

Example. For a very simple example involving only two variables, consider $T = 5(t - 32)/9$ which changes fahrenheit degrees (t) to centigrade degrees (T). It is possible to plot T as ordinate against t as abscissa on rectangular coordinate paper, thereby obtaining a straight line from which the value of T for any given value of t within the range of the graph can be obtained. An alignment chart of the type shown in Fig. 1

$T = \frac{5}{9}(t-32)$ or $t = \frac{9}{5}T + 32$

FIG. 1

can be used to give the same information. Corresponding values of t and T are marked along a single line. This alignment chart has the advantages that it is easier to use, that it is more compact, and that interpolation is usually more accurate on it than on the graph in rectangular coordinates.

An alignment chart giving the logarithms to five places of all five-figure numbers may be printed in eight pages whereas the corresponding tables require much more space. It is, however, more difficult to construct. Charts of this type represent equations of the form

$$y = f(x) \tag{1}$$

where $f(x)$ is a function of the independent variable x, and y is the dependent variable.

58. FUNCTIONS OF THREE VARIABLES

If a problem is governed by an equation of the form $F(x, y, z) = 0$ where $F(x, y, z)$ is any function of the three variables x, y, and z (at least one of which is a dependent variable) then it *may* be possible to construct an alignment chart of the equation. Whether or not the chart *can* be constructed depends on the form of the equation. Below are listed some important forms for which it is possible to construct a chart.

Type I. $$f_1(x) = f_2(y) + f_3(z) \qquad (2)$$

where f_1, f_2, and f_3 are any functions of x, y, and z, respectively; for example, $2x + 3 = 5y^2 + 9 \log z$ is an equation of *Type I*. The alignment chart consists of three parallel straight lines constructed as follows:

Let $f_2\,(y')$ and $f_2\,(y'')$ be the largest and smallest values respectively of $f_2\,(y)$ which it is desired to have on the chart. Choose a *scale factor* m_y so that $m_y\,[f_2\,(y') - f_2\,(y'')]$ is equal to or less than the length which the scale can have on the paper. Plot along a straight line $Y = m_y f_2\,(y)$ from $f_2\,(y'')$ to $f_2\,(y')$, placing the corresponding values of y beside several points in order to have a scale.

At an arbitrary distance d from the Y scale, erect a parallel (Z) scale and repeat the above process, using an appropriate scale factor m_z for the Z scale. It is not necessary to have any point on the Z scale opposite any particular point on the Y scale.

At a distance $m_y d/(m_y + m_z)$ from the Y scale draw a line parallel to Y and Z and use this for the X scale. Let y_0 and z_0 be any two values of y and z, respectively; join the point on the Y scale corresponding to y_0 with that on the Z scale corresponding to z_0 by a straight line and mark the point x_0 where this straight line crosses the X scale. Compute from the original equation $f_1\,(x) = f_2\,(y) + f_3\,(z)$ the value of x ($= x_0$) when $y = y_0$ and $z = z_0$. Then using a scale factor $m_x = m_y m_z/(m_y + m_z)$, plot $X = m_x f_1\,(x)$ in such a way that, when $x = x_0$, the point obtained from $X = m_x f_1\,(x)$ will coincide with the point obtained previously for x_0. The alignment chart is now constructed. *Any straight line will cut the scales Y, X, and Z at points corresponding to values of y, x, and z which will satisfy the basic equation $f_1\,(x) = f_2\,(y) + f_3\,(z)$.*

Example. To plot an alignment chart on 8 1/2 by 11 in. paper for Ohm's law which for a simple electric circuit is $e = ri$. r is to vary between 10 and 100 ohms and i between 1 and 3 amp. Taking the logarithm of each side of the equation, there is obtained

$$\log e = \log r + \log i$$

which is an equation of Type I, with e, r, and i taking the places of x, y, and z respectively. Log e corresponds to $f_1\,(x)$, $\log r$ to $f_2\,(y)$, and $\log i$ to $f_3\,(z)$. When $r = 100$, $\log r = 2$, which corresponds to $f_2\,(y')$; when $r = 10$, $\log r = 1$ which corresponds to $f_2(y'')$. Taking 10 in. as the length of the scale, $m_r(2 - 1) = 10$, or $m_r = 10$, where m_r is the scale factor denoted by m_y in the general discussion. Plotting $m_r \log r$ or $10 \log r$ from $r = 10$ to $r = 100$, the R scale of Fig. 2 is obtained.

Likewise m_i, corresponding to m_z in the general discussion, is found from $m_i\,(\log 3 - \log 1) = 10$, or $m_i = 20.96$. Construct the I scale 6 in. from the R scale, that is, plot $20.96 \log i$ from $i = 1$ to $i = 3$ along a line parallel to the R scale at a perpendicular distance $d = 6$ in. away from the latter.

Now erect a third scale (E), between and parallel to R and I, at a distance $m_r d/(m_r + m_i) = 60/30.96 = 1.94$ in. from R. Take any values of r and i, say $r = 50$ ohms and $i = 2.5$ amp, and join by a straight line the point corresponding to $r = 50$ on the R scale with the point corresponding to $i = 2.5$ on the I scale. The point where this line crosses the E scale corresponds to $e = 50 \times 2.5 = 125$ volts. Mark it. From this point on the E scale, plot upwards $m_e \log e$ from $e = 125$ to $e =$ higher values, and from the same point plot downwards $m_e \log e$ from $e = 125$ to $e =$ lower values. The value of m_e is $m_e = m_r m_i/(m_r + m_i) = 209.6/30.96 = 6.77$.

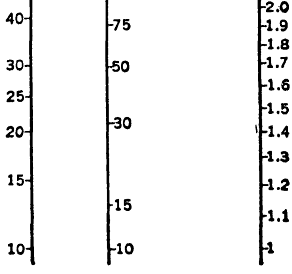

FIG. 2

The alignment chart is now completed. By joining by a straight line (preferably scratched on the bottom of a piece of celluloid or other transparent material to facilitate interpolation) any point on one scale with any point on either other scale, the line passes through a point on the third scale such that the three points correspond to values of e, r, and i satisfying $e = ri$.

The equation $pv = RT$, where R is a constant and p, v, and T are variables, is frequently met in thermodynamics. Let T, p, and v correspond to x, y, and z, respectively, and take the logarithm of both sides. Then $\log R + \log T = \log p + \log v$, whence, with $\log R + \log T$ corresponding to $f_1(x)$, $\log p$ to $f_2(y)$ and $\log v$ to $f_3(z)$, the procedure in the above example may be followed almost identically to obtain the alignment chart.

Type II.
$$f_1(x) = \frac{f_2(y)}{f_3(z)} \tag{3}$$

where $f_1(x)$ is any function of x, $f_2(y)$ any function of y, and $f_3(z)$ any function of z. The alignment chart is called a Z chart, on account of its shape. Draw two parallel lines Y and Z at a convenient distance from each other and choose scale factors m_y and m_z as before, except that the minimum values of $f_2(y)$ and $f_3(z)$ should be taken zero. Plot $m_y f_2(y)$ along Y. Plot $m_z f_3(z)$ *in the opposite direction* along Z. That is, if $m_y f_2(y)$ is plotted from bottom to top of Y (zero value at bottom), then $m_z f_3(z)$ should be plotted from top to bottom (zero value at top). Join the point corresponding to $f_2(y) = 0$ with the point corresponding to $f_3(z) = 0$ by a straight line X. This line will be of length k. Plot $k\, m_y f_1(x)/[m_z + m_y f_1(x)]$ along X, taking *as origin* the point corresponding to $f_2(y) = 0$, which is one end of the X scale. The alignment chart is now drawn; any straight line passing through the scales cuts them at points whose corresponding values of x, y, and z satisfy the original equation.

It should be noted that (1) Type II includes equations of the form $f_1(x) = f_2(y)\,F_3(z)$, where $F_3(z)$ is a function of z only, since these can be thrown into the form previously given by replacing $F_3(z)$ by $1/f_3(z)$; (2) any equation of Type II can be made an equation of Type I by taking the logarithm of both sides, for then $\log f_1(x) = \log f_2(y) - \log f_3(z)$ which is of Type I; (3) on Z charts the X scale will always contain all values of $f_1(x)$ from 0 to ∞, which may be an advantage.

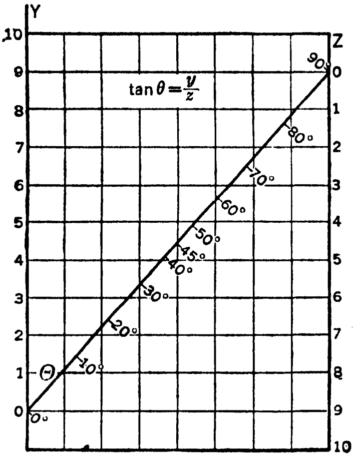

FIG. 3

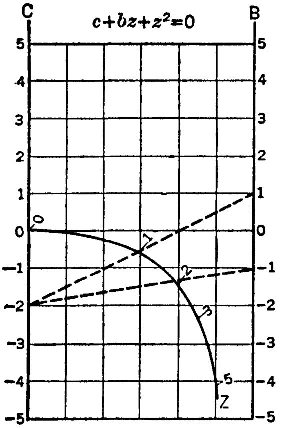

FIG. 4

Example. In a right triangle $\tan\theta = y/z$ where θ is an angle (not 90°), y is the length of the opposite side of the triangle, and z that of the side adjacent to θ. Here θ corresponds to x, $\tan\theta$ to $f_1(x)$, $f_2(y)$ is y, and $f_3(z)$ is z. Scales Y and Z will be uniform. The chart is shown in Fig. 3.

Type III.
$$f_1(x)\,f_4(z) + f_2(y)\,f_5(z) + f_3(z) = 0 \tag{4}$$

The alignment chart usually consists of two straight lines and a curved scale. (Types I and II are special cases of Type III, in which the curved scale becomes straight.)

Draw two parallel lines X and Y, as far apart as is convenient. Plot $m_x f_1(x)$ along X and $m_y f_2(y)$ along Y, choosing suitable scale factors m_x and m_y as before, and placing the respective origins opposite each other. (See Fig. 4.) Now draw two straight lines, one perpendicular to X and Y and passing through both origins, the other parallel to

X and Y and halfway between them. These are temporary construction axes which may be called U and V, respectively. Plot in the usual manner, with reference to these rectangular axes, the curve whose coordinates are

$$u = -k \frac{m_y f_4(z) - m_x f_5(z)}{m_y f_4(z) + m_x f_5(z)} \quad (5a) \quad \text{and} \quad v = \frac{-m_x m_y f_3(z)}{m_y f_4(z) + m_x f_5(z)} \quad (5b)$$

where k is the distance from either X or Y to V. Mark points with the corresponding values of z. The curve thus obtained and the X and Y scales form the desired alignment chart. A straight line passing through points on any two of the scales will intersect the third scale at such a point that the corresponding values of x, y, and z satisfy the given equation. The equations for u and v show that the ratio m_x/m_y is important in determining the shape of the curved Z scale. It is frequently desirable to try different convenient values of m_x/m_y, sketching the curve roughly each time, to obtain a Z scale of good shape so far as accuracy and ease of reading are concerned.

Example. To draw an alignment chart on $8^1/_2$ by 11 in. paper for the equation $c + bz + z^2 = 0$ which will give the real roots of this quadratic equation for b between -5 and $+5$, c between the same limits. Comparing this with the typical equation of Type III, c, b, z correspond to x, y, z, respectively, c to $f_1(x)$, b to $f_2(y)$, z^2 to $f_3(z)$, 1 to $f_4(z)$, z to $f_5(z)$. Taking 10 in. as a desirable length for the B and C scales, $m_b = 10/[5 - (-5)] = 1$ and $m_c = 1$ likewise. Then, taking $k = 3$ in.,

$$u = -3\left[\frac{1-z}{1+z}\right] \quad (6a) \quad \text{and} \quad v = \frac{-z^2}{1+z} \quad (6b)$$

Plotting the curve given by these coordinates on the construction axes U, V, Fig. 4 is obtained. Only positive values of z are shown on the Z scale; for negative roots of $c + bz + z^2 = 0$, reverse the sign of the positive roots of $c - bz + z^2 = 0$.

Type III (a).

$$\frac{f_4(z)}{F_1(x)} + \frac{f_5(z)}{F_2(y)} + f_3(z) = 0 \quad (7)$$

which is the same as the original Type III equation except that $F_1(x)$ has been written for $1/f_1(x)$ and $F_2(y)$ for $1/f_2(y)$. The alignment chart may be composed of two *intersecting* straight lines and a curved scale.

Draw an X scale horizontal and a Y scale vertical, and take the intersection as origin. Choose scale factors m_x and m_y, and call $1/m_x$ one unit along X and $1/m_y$ one unit along Y. Plot the curve whose coordinates are

$$x = -f_4(z)/f_3(z) \quad (8a) \quad \text{and} \quad y = -f_5(z)/f_3(z) \quad (8b)$$

marking points with corresponding values of z. This curve is the Z scale. Now plot $m_x F_1(x)$ along X and $m_y F_2(y)$ along Y, obtaining the X and Y scales. The alignment chart is complete; a straight line crossing the scales will cut them at points corresponding to values of x, y, and z satisfying the basic equations.

Example. Take the previous example $c + bz + z^2 = 0$ and assume that an alignment chart is desired for large values of c and b. Write the equation in the form

$$\frac{1}{x} + \frac{z}{y} + z^2 = 0$$

where $x = 1/c$, $y = 1/b$,

$x = F_1(x)$, $y = F_2(y)$, $1 = f_4(z)$, $z = f_5(z)$, $z^2 = f_3(z)$

The chart is shown in Fig. 5.

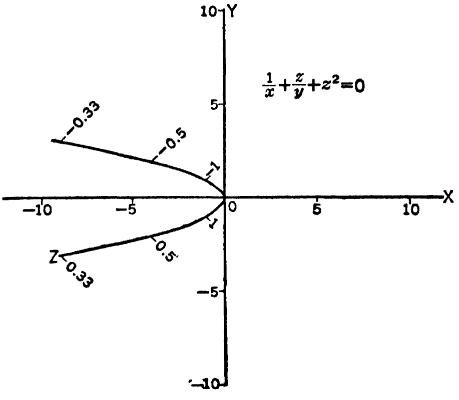

FIG. 5

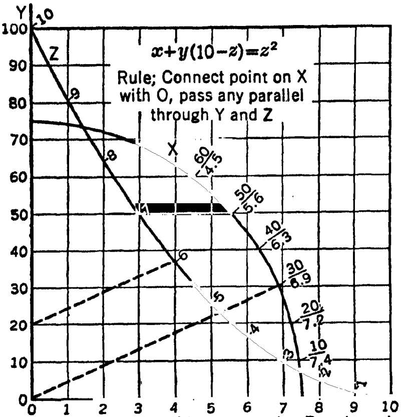
It is seen from this example that a chart of this type has a complementary relation to that of Fig. 4. Large values of b and c will not fall conveniently on the latter but will on the former (since small x and y correspond to large c and b). The choice of form for a chart will thus depend on ranges of the variables and accuracy desired.

Type III (b).

$$f_2(y) + f_1(x)\,F_1(z) = F_2(z) \quad (9)$$

which can be obtained from the original Type III equation by dividing by $f_5(z)$ and writing $F_1(z)$ for $f_4(z)/f_5(z)$ and $F_2(z)$ for $-f_3(z)/f_5(z)$. In this form the equation is conveniently arranged for the construction of an alignment chart consisting of a straight scale, a scale on the arc of a circle, and a curved scale.

Plot in rectangular axes the curve the abscissa of any point of which is $F_1(z)$ and the ordinate $F_2(z)$. The unit for abscissas need not be the same as the unit for ordinates (i.e., scale factors should be chosen so that the curve fits on the paper for the range of z to be considered) but the same units must be used throughout the construction of the chart. The curve thus found is the Z scale, and values of z should be marked beside the points to which they correspond to give the scale.



(Auxiliary scale used in constructing Z scale and X scale; latter is marked to show slope in units used on Y scale and auxiliary scale.)

FIG. 6

Take the vertical axis as the Y scale and plot $m_y f_2(y)$ along it, m_y being the scale factor for ordinates. Now with the origin as center draw an arc of a circle, cutting the horizontal axis at some point from which a scale is to be laid off along this arc in the counter-clockwise direction, such that the slope of the line from any point on the scale to the origin is $f_1(x)$. The scale thus formed is the X scale. This alignment chart differs from those previously considered in that two straight lines are needed to determine a set of points such that the corresponding values of x, y, and z satisfy the original equation. Draw one line from a point on the X scale to the origin. Then any *parallel* line will cut the Y and Z scales in points which, taken with the original X point, satisfy the basic equation.

Example. $y + x(10 - z) = z^2$.

Here $y = f_2(y)$, $x = f_1(x)$, $10 - z = F_1(z)$, $z^2 = F_2(z)$. The chart is shown in Fig. 6.

Type IV. $X_1 Y_2 Z_3 + X_2 Y_3 Z_1 + X_3 Y_1 Z_2 - X_1 Y_3 Z_2 - X_2 Y_1 Z_3 - X_3 Y_2 Z_1 = 0$ where X_1, X_2, and X_3 are functions of x only, Y_1, Y_2, Y_3 of y only, etc. The equation may be written in determinant (q.v.) form:

$$\begin{vmatrix} X_1 & X_2 & X_3 \\ Y_1 & Y_2 & Y_3 \\ Z_1 & Z_2 & Z_3 \end{vmatrix} = 0 \qquad (10)$$

This is the most general equation in three variables which can be represented by an alignment chart, which latter will consist of the most general case of three curved scales. All the preceding types are special cases of Type IV. *Unless an equation can be reduced to the form of Type IV, no alignment chart can be made.* General rules for determining whether this is possible or not cannot be given; a trial-and-error method must be used. Rules for constructing alignment charts for equations of Type IV which do not reduce to one of the special cases (Types I, II, and III) previously given will be found in texts on nomograms.

59. FUNCTIONS OF FOUR VARIABLES

Functions of four (sometimes more) variables can be handled in several ways. One method is to construct charts which may be moved with respect to one another. A slide rule (not usually considered an alignment chart) is a special and simple illustration of sliding charts, each comprising one scale.

Method I. One method is based on writing a given equation $F(x, y, z, t) = 0$ in the form of two equations by introducing a new variable u: $F_1(x, y, u) = 0$ and $F_2(z, t, u) = 0$. The latter two equations are simply simultaneous equations from which u may be eliminated to get $F(x, y, z, t) = 0$, the original equation, but they must be so chosen that the U scale can be made common to their charts.

Example. $f_1(x) = f_2(y) + f_3(z) + f_4(t)$

where $f_1(x)$ is any function of x, etc. Construct a chart for the equation $f_3(z) + f_4(t) = u$ by the rules for equations in three variables of Type I. Now construct a chart for

$f_1(x) = f_2(y) + u$ by the same rules, making the U scale common to the two three-variable charts. No graduations are necessary on the U scale in this case.

To use the chart, draw a straight line through points corresponding to z on the Z scale and t on the T scale and note where this line crosses the U scale. Through the latter point and a point corresponding to y on the Y scale, pass a line which will cut the X scale at a point corresponding to the value of x which satisfies the basic equation.

Example.
$$\frac{x}{y} = \frac{a + z}{a + t}$$

where a is a fixed constant. Each side of the equation may be set equal to u. Then a Z chart can be constructed for $x/y = u$ and another for $(a + z)/(a + t) = u$, with the U scale common. (See Type II of functions of three variables.) A straight line passing through points on the X scale corresponding to x and on the Y to y determines a point on U. Through the latter and a point on the Z scale corresponding to z a straight line may be passed which will cut the T scale at a point corresponding to a value of t which satisfies the equation.

Method II. Another method of constructing a chart for a function of four variables is to write the equation (if possible) in the form given for Type IV of functions of three variables with Z_1, Z_2, and Z_3 replaced by H_1, H_2, and H_3 where each H is some function of z and t (but not of x and y). If this can be done, then for a given value of t, a Z scale can be constructed, for another value of t, a different Z scale, etc. Likewise for fixed values of z, various T scales can be drawn. Thus a family of Z and T scales is obtained so that, given a value of t, the proper Z scale can be chosen, and used with the X and Y scales in the same manner as in the case of a three-variable chart.

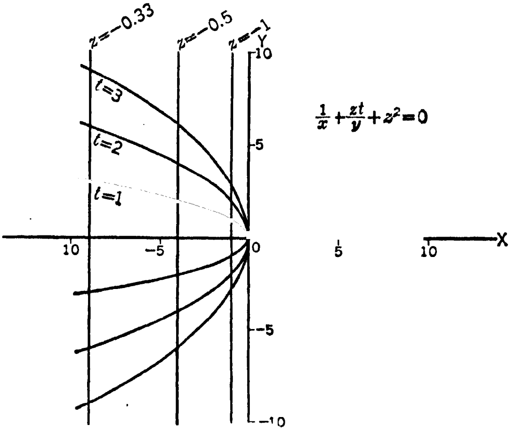


Fig. 7

Example.
$$\frac{1}{x} + \frac{zt}{y} + z^2 = 0$$

When $t = 1$ this becomes the equation charted in Fig. 5 as an example of Type III (a) of a function of three variables. When $t = 2, 3, 4, \ldots$, the same X and Y scales may be used, but a different Z scale is obtained for each value of t. Points on the Z scales representing the same value of z may be connected by curves, giving a family of curves. The chart is shown in Fig. 7.

Method III (Proportional Charts). If an equation is of the form

$$\frac{f_1(x)}{f_2(y)} = \frac{f_3(z)}{f_4(t)} \tag{11}$$

then it is in the form of a simple proportion $(a/b = c/d)$.

Construct two sets of perpendicular axes, X and Y and Z and T (the two sets may coincide) such that Z is parallel to X and Y to T. Plot $f_1(x)$ along X, using any convenient unit, and $f_3(z)$ along Z, using the same unit. Plot $f_2(y)$ along Y (a different unit may be used) and $f_4(t)$ along T using the same unit as used along Y. Connect any point on X with any point on Y. Any *parallel* line will cut Z and T at points corresponding to values of z and t which with the values of x and y given by the first line will satisfy the basic equation.

Example.
$$\frac{x}{y} = \frac{3 + z^2}{\cos\theta}$$

Here $x = f_1(x)$, $y = f_2(y)$, $3 + z^2 = f_3(z)$ and θ, $\cos\theta$ correspond to t, $f_4(t)$, respectively. The chart is shown in Fig. 8.

Another form of proportional chart can be used when the basic equation can be thrown into the form

$$f_1(x) - f_2(y) = f_3(z) - f_4(t) \tag{12}$$

Construct two pairs of axes, X and Y, Z and T, all parallel. Make the distance between X and Y the same as that between Z and T (which may be zero). Plot, using the same unit throughout, $f_1(x)$ along X, $f_2(y)$ along Y, etc. Join any point on X with any point on Z. Any *parallel* line will cut Y and T at points such that the corresponding values of z and t will satisfy the basic equation. Note that any equation of the form first considered under Method III may be thrown into the form here considered by taking the logarithm of both sides.

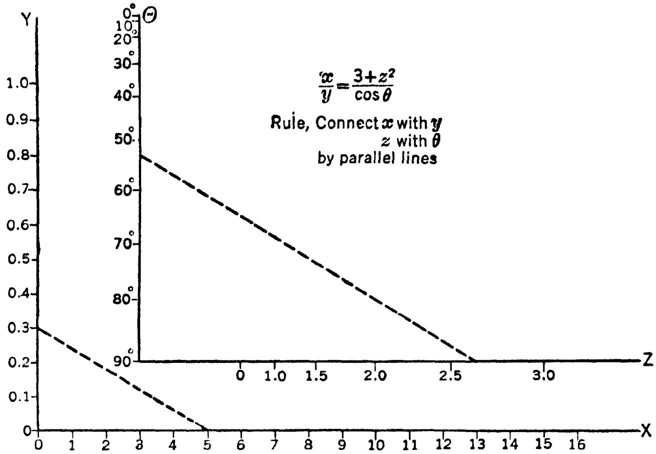

FIG. 8

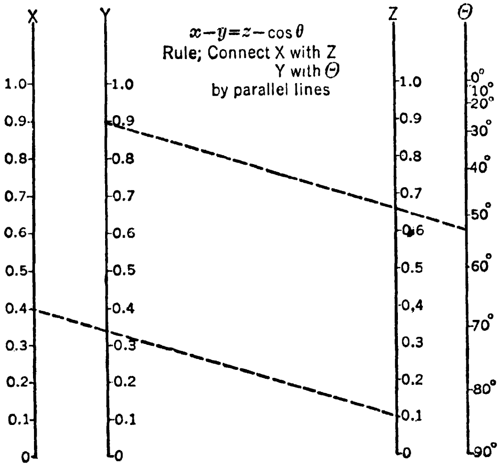

FIG. 9

Example. $x - y = z - \cos\theta$

The chart is shown in Fig. 9.

PRECISION OF MEASUREMENTS

By J. L. Barnes and Churchill Eisenhart

To increase the reliability of the result of a direct physical measurement the measuring operation is applied to the same quantity more than once. It is important to know how to combine the results of such repeated observations to find the *best estimate* of the *true* value of the quantity measured. Likewise the *risk* incurred in accepting the estimate should be determined since the amount allowable will vary with the purpose for which the estimate is to be used.

60. OBSERVATIONS AND ERRORS

The Error of an Observation is the observed value of the quantity minus the true value, e.g., $e_i \equiv m_i - m$, $i = 1, 2, \ldots n$, where the m_i's are the observed values, the e_i's the errors, and m the true value which is unknown.

Errors are classified as accidental and systematic. *Accidental errors* are those which in a large number of measurements are as often negative as positive. They affect the arithmetic mean but little. All other errors are classed as *systematic*. Systematic errors due to the same cause affect the mean in the same sense, and do not tend to balance each other, but rather give a definite bias to the mean.

It is necessary to eliminate all systematic errors if accurate results are to be secured. In a search for systematic errors each possible source should be varied separately. When systematic errors have been removed there always remains a residual or accidental variability which may be reduced by refinement of apparatus and increased skill in manipulation but which cannot be completely eliminated.

Best Estimate and Measured Value. All systematic errors having been eliminated, it is possible to consider the individual repeated measurements of a quantity with a view to securing the "best estimate of the true value" of the quantity and assessing the degree of reproducibility which has been obtained. The final result will then be expressed in the form $E \pm L$, where E is the best estimate of the true value and L represents the characteristic limit of variation associated with a certain risk. In this connection, it seems appropriate to remark that the entire result, $E \pm L$, is the measured value of the quantity, and not merely E.

The Arithmetic Mean. If a large number of measurements have been made to determine directly the unknown magnitude, m, of a certain quantity, all measurements having been made *with equal skill and care*, the *best estimate* of m is the arithmetic mean, $\bar{m}$, of all the measurements.

$$\bar{m} = \frac{1}{n}\sum_{i=1}^{n} m_i \qquad (1)$$

Standard Deviation, in the theory of least squares, is defined as the *root-mean-square* of the deviations e_i of a set of observations from the true value. In the equation

$$\sigma = \left(\frac{1}{n}\sum_{i=1}^{n} e_i^2\right)^{1/2} \qquad (2)$$

σ may be considered, in the language of mechanics, as the radius of gyration of a set of n equal particles, with respect to a given centroid axis.

Since neither the true value, m, nor the errors of observation, $e_i = m_i - m$, are known, the deviations from the mean, $x_i \equiv m_i - \bar{m}$, $i = 1, 2, \ldots, n$, shall henceforth be referred to as errors. Likewise, for the value of σ, the following will be used:

$$\sigma = (n-1)^{-1/2}\left[\sum_{i=1}^{n}(m_i - \bar{m})^2\right]^{1/2} = (n-1)^{-1/2}\left(\sum_{i=1}^{n} e_i^2\right)^{1/2} \qquad (3)$$

in which n is replaced by $n - 1$ since one degree of freedom is lost by using $\bar{m}$ instead of m, $\bar{m}$ being related to the m_i's.

61. THE PROBABLE ERROR

Relative Frequency of Errors. The most prominent frequency function of practical statistics is the *Gauss-Laplace* law of frequency of errors,

$$y = \frac{1}{\sigma\sqrt{2\pi}} e^{-x^2/2\sigma^2} \qquad (4)$$

The curve with this equation (Fig. 1) is known in statistics as the *normal probability curve.* It is also frequently written:

$$y = \frac{1}{\sqrt{\pi}} h\, e^{-h^2x^2} \tag{5}$$

where $2h^2\sigma^2 = 1$, or $h = 1/(\sqrt{2}\sigma)$, and y represents the proportionate number of errors of value x. Thus the area under the curve is unity. The dotted curve (Fig. 1) is also an error distribution curve with a greater value of h. It will be observed that the greater the value of h the more closely are the errors clustered about the maximum ordinate, which is at $x = 0$. Hence h may be considered as a *precision index* and is a measure of the concentration of observations about their mean. Also, h is in inverse relation to σ.

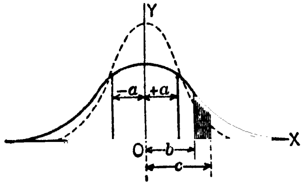

FIG. 1

Probability. The proportionate number of errors whose values lie between $x = -a$ and $x = a$ (Fig. 1) is

$$P = \frac{h}{\sqrt{\pi}} \int_{-a}^{+a} e^{-h^2x^2}\, dx = \frac{2}{\sqrt{\pi}} \int_0^{ha} e^{-h^2x^2}\, d(hx) \tag{6}$$

where P is the probability of an observational error, x, having a value between $-a$ and a. In a similar manner the shaded area in Fig. 1 represents the relative frequency or probability of errors between b and c.

Values of P corresponding to values of ha given in Table I are published by James Burgess in the *Transactions of the Royal Society,* Edinburgh, **39,** 257, 1900, and in the Smithsonian Tables.

Table I. Values of $P = \frac{2}{\sqrt{\pi}} \int_0^{ha} e^{-h^2x^2}\, d(hx)$

* $ha = 0.47694 \frac{a}{r} = \frac{1}{\sqrt{2}} \frac{a}{\sigma}$

Probable Error, r. In the publication of results of measurements it has been customary in the United States to express these results in the form $E \pm r$, where r is the *probable error of a single observation* and is defined as *the number which the actual error may with equal probability be greater or less than.* Thus from (6),

$$\frac{2}{\sqrt{\pi}} \int_0^{hr} e^{-h^2x^2}\, d(hx) = 0.50 \tag{7}$$

and $$hr = 0.47694 \tag{8}$$

or $$r = 0.4769 \times \sqrt{2}\,\sigma = 0.6745\,\sigma \tag{9}$$

In a similar manner it may be observed that 5 per cent of the errors, x, are greater than 2σ, and less than 1 per cent are greater than 3σ. Thus it is possible to evaluate the risk involved in accepting the mean of a number of observations.

From the preceding discussion it follows that

$$r = 0.6745\sigma = 0.6745\,(n-1)^{-\frac{1}{2}}\left(\sum_{i=1}^{n} x_i^2\right)^{\frac{1}{2}} \tag{10}$$

This is the standard formula for r and should be used for results which are to be published. For rapid comparisons, however, the following approximate formula due to Peters is useful:

$$r \approx 0.8453\,[n(n-1)]^{-\frac{1}{2}}\sum_{i=1}^{n} |x_i| \tag{11}$$

The Standard Deviation of the Arithmetic Mean, $\sigma_{\bar{m}}$, as calculated from data, is related to the standard deviation, σ, by the formula

$$\sigma_{\bar{m}} = n^{-\frac{1}{2}}\sigma = [n(n-1)]^{-\frac{1}{2}}\left(\sum_{i=1}^{n} x_i^2\right)^{\frac{1}{2}} \tag{12}$$

From this formula and Tables I and II the limits corresponding to given risks can be determined as indicated above. It is evident that the stability of the mean increases with n, i.e., the effect of the erratic behavior of single cases decreases with increase of n.

The Probable Error of the Arithmetic Mean as calculated from data, $r_{\bar{m}}$, is then given by

$$r_{\bar{m}} = 0.6745\,[n(n-1)]^{-\frac{1}{2}}\left(\sum_{i=1}^{n} x_i^2\right)^{\frac{1}{2}} \tag{13}$$

and Peters' formula for the approximate value is:

$$r_{\bar{m}} \approx 0.8453\,[n^2(n-1)]^{-\frac{1}{2}}\sum_{i=1}^{n} |x_i|.$$

62. APPLICATIONS

Example. The following are ten measurements, m_i, of the length of a base line. Below are given the values of the residuals, x_i, and their squares. m_i: 455.35, 455.35, 455.20, 455.05, 455.75, 455.40, 455.10, 455.30, 455.50, 455.30

Arithmetic mean, $\bar{m} = 455.330.$

x_i: 0.02, 0.02, − 0.13, − 0.28, 0.42, 0.07, − 0.23, − 0.03, − 0.17, − 0.03.

x_i^2: 0.0004, 0.0004, 0.0169, 0.0784, 0.0049, 0.0529, 0.0009, 0.0289, 0.0009.

Hence: $\sum_{i=1}^{10} x_i^2 = 0.3610$, and $\sum_{i=1}^{10} |x_i| = 1.40$.

So by the standard formulas, $r = 0.6745\,(9)^{-\frac{1}{2}}(0.3610)^{\frac{1}{2}} = 0.13$, $r_{\bar{m}} = (10)^{-\frac{1}{2}} r = 0.042$.

By the approximate formulas, $r \approx 0.8453\,(90)^{-\frac{1}{2}}(1.40) = 0.12$, $r_{\bar{m}} \approx 0.039$.

For the best estimate of the base line, the result is 455.330 with probable error ± 0.042 (using result given by standard formula), usually written 455.330 ± 0.042. Note that five of the residuals are numerically less than the probable error of a single observation. In fact, in any considerable number of observations it should be the case that half of the residuals are less than the probable error.

It can be shown that the standard deviation, σ, of a *rounded number* (p. 2–05) due to rounding is $\sigma = 0.2887\,w$, where w is a unit in the last place retained. Consequently, the probable error of a rounded number due to rounding is:

$$r = 0.6745 \times 0.2887\,w = 0.1947\,w.$$

Weighted Observations. Sometimes, notwithstanding the care with which observations are taken, there are reasons for believing that certain observations are better than others. In such cases the observations are given different weights, that is, are counted different numbers of times, the weights or numbers expressing their relative practical worth. If there are n weighted observations, m_i, with weights, p_i, these being made directly on the same quantity, then the best estimate of the true value of the quantity is the *weighted arithmetic mean*, $\bar{m}$.

$$\text{Weighted mean, } \bar{m} \equiv \sum_{i=1}^{n} p_i\,m_i \Big/ \sum_{i=1}^{n} p_i$$

For the set of weighted observations we have

$$r = 0.6745\,(n-1)^{-\frac{1}{2}}\left(\sum_{i=1}^{n} p_i x_i^2\right)^{\frac{1}{2}}$$

as the probable error of an observation of unit weight, and

$$r_{\bar{m}} = 0.6745\left[(n-1)\sum_{i=1}^{n} p_i\right]^{-\frac{1}{2}}\left(\sum_{i=1}^{n} p_i x_i^2\right)^{\frac{1}{2}}$$

as the probable error of the arithmetic mean of weighted items, in which

$$x_i \equiv m_i - \sum_{i=1}^{n} p_i m_i \Big/ \sum_{i=1}^{n} p_i.$$

Example. Let six observations on the same quantity be made, with weights, p_i, the sum of these weights being 21 (see tabulation below). The sum of the weighted observations, $\sum_{i=1}^{6} p_i m_i$, is 3741.36. The best estimate of the value of the observed quantity is $\bar{m} = 3741.36/21 = 178.16$. Subtracting this from each m_i gives the residuals x_i. The sum of the weighted squares of the residuals, $\sum_{i=1}^{6} p_i x_i^2$, is 62.95. Then the preceding formulas give the probable error of an observation of weight unity as $r = 2.39$ and the probable error of the weighted mean as $r_{\bar{m}} = 0.52$. The final result then is 178.16 ± 0.52.

p_i:	5	4	1	4	3	4

Probable Error in a Result Calculated from the Means of Several Observed Quantities. Let Z be a sum or difference of m (means of) observed *independent* quantities. Then if r_j, $j = 1, 2, \ldots, m$, be the probable errors in these means, the probable error in Z is equal to $\left(\sum_{j=1}^{m} r_j^2\right)^{\frac{1}{2}}$.

Let $Z = Az$, where z is (the mean of) an observed quantity, and A, a known number. Let r be the probable error in z. Then the probable error in Z is Ar.

Let Z be any differentiable function of the (means of) *independently* observed quantities, z_j, whose probable errors are r_j. Then the probable error in Z is equal to

$$\left[\sum_{j=1}^{m}\left(\frac{\partial Z}{\partial z_j}\right)^2 r_j^2\right]^{\frac{1}{2}},$$

e.g., if Z be the product of (the means of) two independently observed quantities, z_1, z_2, whose probable errors are r_1, r_2, respectively, then the probable error in Z is equal to

$$(z_1^2 r_2^2 + z_2^2 r_1^2)^{\frac{1}{2}}$$

A Note on the Interpretation of Standard Deviation, Probable Error, etc. The theory underlying the foregoing development depends upon the following assumptions: (1) A large number of observations have been made. (2) The observations have been made with equal care and skill so that: (2.1) there are approximately an equal number of readings above and below the mean (except in the case of weighted items), and (2.2) the individual deviations from the mean are small in most cases, and (2.3) the number of deviations diminishes rapidly as their size increases.

The extent to which the observed data satisfy the above assumptions is a measure of the extent to which we are justified in using the Gauss error curve, which is consistent with the statement that $\bar{m}$ is the best estimate of the true value m, and which leads to the factor 0.6745 used in computing probable error. Recent work has shown that, even if we were not justified in assuming the Gaussian distribution of errors, the arithmetic mean still remains the best estimate we have for m. Therefore, there is little difficulty in this regard, especially since "errors" appear to follow the Gaussian distribution as closely as any other we know. Our difficulties enter in connection with the factor 0.6745 and the accuracy of the σ, as estimated from the data.

If the number of observations is small the estimate of the standard deviation of the possible infinity of observations (of which those at hand are a sample) is itself subject to considerable error. For example, for $n = 3$ the standard error of the standard deviation is as large as the standard deviation itself, and hence the probable error calculated from $r = 0.6745\sigma$ would not be very reliable. The following table * will illustrate this. The second and third columns give the probability that the probable error of a single observation should be out 20 and 50 per cent, respectively.

n	20 per cent	50 per cent	n	20 per cent	50 per cent
5	0.64	0.24	30	0.12	0.00014
10	.40	.034	40	.076	8×10^{-6}
15	.29	.008	50	.047	6×10^{-7}
20	.21	.0002	100	.0050	

From this table it is clear that with 10 observations the odds are only 3 to 2 that the calculated probable error is within 20 per cent of the correct value, and about 30 to 1 that it is within 50 per cent of the correct value. Of course, the probable error of the mean will be correspondingly out.

The probable error of a single observation is sometimes *defined* very simply by

$$r \equiv 0.6745\,(n-1)^{-1/2}\left(\sum_{i=1}^{n} x_i^2\right)^{1/2}$$

and the probable error of the mean is then

$$r_{\bar{m}} = 0.6745\,[n(n-1)]^{-1/2}\left(\sum_{i=1}^{n} x_i^2\right)^{1/2}$$

which does not impose any condition with regard to the distribution. In this sense it is a measure of the way the values cluster about the mean value, and is in no way superior to the h defined earlier, and is inferior to just giving σ itself, since the even wager which brings in 0.6745 is no longer important. This use of the probable error as a *precision index* seems to be customary in the United States, and, indeed, it is as useful as any other index (except σ, from which it differs by merely a numerical multiplier) in connection with results from only a few observations, from results calculated from weighted items, etc. But it must be remembered that in this connection it cannot be used to draw inferences about what might happen if the measurements were repeated a large number of times.

For those who are interested in drawing such inferences, it seems fitting to remark that the use of Table I is quite legitimate for $100 < n$, and that for $30 < n < 100$ the tables may be used provided σ is multiplied by $(n-3)^{-1/2}$. For $n < 30$, a rough estimate can be obtained from the fact that the percentage of cases lying outside the range, mean $\pm \lambda\sigma$, is $< 100\,\lambda^{-2}$ for $1 < \lambda$. A striking property of this inequality due to Tchebycheff is that it is independent of the nature of the distribution assumed.

PHYSICAL UNITS AND STANDARDS

DIMENSION SYSTEMS

1. PHYSICAL QUANTITIES AND THEIR RELATIONS

Mathematics is concerned with relations between numerical quantities, either constant or varying in a specified manner over a specified range of values. The numerical values are unique, absolute, and the same all over the world, being the expression of a fundamental perception of the mind. Any *mathematical equation* defines the values of one numerical quantity, known as the dependent, in terms of constants and one or more other numerical quantities, known as the independent variables, as for example

$$z = y^2 + 3x + 4, \quad y = c\cdot\int_0^x \frac{x^2}{\cos x}\,dx \tag{1}$$

Physics, comprising the knowledge of inanimate nature and her laws, is concerned fundamentally with the measuring of the various quantities founded or created by definition, as for example, *length, mass, electric charge.* In order to specify a *physical quantity* it is not sufficient to state merely a number. The value of a physical quantity can be determined only by comparison of the sample with a known amount of the same quantity, which process is *measuring.* The reference amount is called a unit, and the result of any measurement must be a statement of " how many times the sample was found to contain the reference amount." Thus a physical quantity Q naturally appears to be the product of a numerical value N and a unit U,

$$Q = N\cdot U \tag{2}$$

as for example: The length of a particular rod is 3.5 ft, or the rod is 3 $^1/_2$ times the length of 1 ft. Obviously, the reproduction of a unit must be possible at any time in order to facilitate correct measurements. This is being done by means of the " standards," which are simply a set of fundamental unit quantities kept under normalized conditions in order to preserve their values as accurately as facilities permit.

Any physical relation must be the result of a more or less obvious measurement, so that equations in physics are not merely numerical relations, but express dependences between physical quantities. Mathematics does not know "standards"; physics cannot be without "standards." The fact that physics often uses the methods of mathematics must not lead to the identification of the two sciences; it is merely an overlapping in the border regions.

Relations between Units. A unit is a particular amount of the physical quantity to be measured, defined in terms of a standard.* The choice of a unit depends on convenience, facility of reproduction, and easy subdivision so as to obtain smaller units if desired. The value of a physical quantity Q must be independent of the units used, so that for two different units of the same type

$$Q = N_1\cdot U_1 = N_2\cdot U_2 \tag{3}$$

The size of the unit and the numerical value of the quantity are inversely related: the larger the unit the smaller the number of units.

A unit relation is an equation between two different units of the same type

$$U_1 = N_{12}\cdot U_2 \tag{4}$$

and serves to convert from one unit U_1 to a different one U_2. The conversion is achieved by replacing U_1, taken as a factor, by its equivalent according to equation 4 so that

$$Q = N_1\cdot U_1 = N_1\cdot(N_{12}\cdot U_2) = (N_1\cdot N_{12})\cdot U_2 \tag{5}$$

As example, express the length 3.5 ft in centimeters. The unit relation is 1 ft = 30.3 cm, and therefore $l = 3.5$ ft $= 3.5 \times (30.3$ cm$) = 106.25$ cm. No error is possible if this rule is followed properly.

---

* S. W. Stratton, Electric Units and Standards, Circular of the Bureau of Standards, No. 60, 1920.

Physical Equations. Relations between physical quantities are usually given in the form of equations. It is always possible, by the proper use of unit relations (see previous paragraph), to express each side in the same units. Since units are to be considered as factors, they may be canceled and a numerical identity must result. This fact always can be used to check the proper numerical relations and the consistency of the units used.

There are two fundamental types of physical equations:

The Mathematical Definition of a physical quantity determines a new quantity uniquely in terms of known quantities. An example is Newton's definition of mass by $f = m \cdot a$, where f is the force and a the acceleration of a moving body. If f and a are measured, m can be computed as a physical quantity with numerical value $\dfrac{N(f)}{N(a)}$ and unit $\dfrac{U(f)}{U(a)} = U(m)$. A definition should be in agreement with all the other known relations in a particular field of science; it can only be of restricted value if it contradicts other relations (see later the "absolute" electric systems).

The Statement of Proportionality defines one physical quantity as linearly depending on a combination of other, known quantities. It is always the result of an experimental investigation. An example is Newton's law of the gravitational force $f = k \dfrac{m_1 m_2}{r^2}$, where m_1 and m_2 are the two masses, r their center distance, and k the proportionality factor. In the case of a proportionality it is permissible to choose arbitrary units for all measurable physical quantities involved and to use the equation as a definition of the proportionality constant which, in general, will be a physical constant with numerical value and unit. In the example the value of k would be

$$\frac{N(f) \cdot N(r^2)}{N(m_1) \cdot N(m_2)} \times \frac{U(f) \cdot U(r^2)}{U(m_1) \cdot U(m_2)} = N(k) \cdot U(k).$$

Most of the fundamental laws of physics are statements of proportionalities, leading to universal physical constants, as for instance the gravitational constant k, the Planck constant h, the gas constant R, the absolute permeability of free space Π_0, and the absolute dielectric constant of free space Δ_0. It may be observed that each branch of physics is represented by at least one fundamental proportionality constant.*

Derived Physical Quantities are, in general, the result of mathematical definitions. The units of derived quantities are expressed from the combinations of the units used in the definition. All proportionality constants logically have to be considered as derived physical quantities.

Fundamental Physical Quantities. The physical quantities, arbitrarily chosen to define new quantities or derived quantities, are called fundamental physical quantities. Their number may vary according to needs and convenience. There is no possibility to designate any physical quantity as absolutely fundamental, or *a priori* fundamental. Quantities which appear to be fundamental in some one special field may be derived quantities in some other field.

2. DIMENSIONS AND DIMENSION SYSTEMS

Definition of Dimension. To choose a unit for a physical quantity one has an infinity of possibilities. The numerous units of length which were in use about 100 years ago present a good practical illustration. Yet all these units have in common the quality of being a distinct length and not, for example, a volume. It is convenient to state this fact by representing with the notation $[L]$ any unit of length whatsoever. The measurement of a physical quantity Q, therefore, leads to the statement

$$Q = N \cdot [Q] \tag{6}$$

where N is a numeric denoting the number of general units $[Q]$ which constitute the total quantity Q. According to Fourier,† who first introduced this concept into the literature, $[Q]$ is called the "dimension" of the quantity Q. Be it clearly understood that dimension is simply the expression of a general unit and therefore a characteristic peculiarity of physical quantities, not occurring in mathematics. Each new physical quantity gives rise to a new "dimension" as for instance time $[T]$, force $[F]$, mass $[M]$, and so on. There are as many dimensions, or general units, as there are kinds of physical quantities.

---

* In the second report of the British Association for the Advancement of Science, Committee on Standards (1873), J. Clerk Maxwell makes a statement in connection with the form of Coulomb's law for magnetic poles, p. 63, about the "absurdity" of a proportionality factor, which arouses very pointed remarks by O. Heaviside, in his Electromagnetic Theory, Vol. 1, p. 118, 1893.

† J. B. J. Fourier, Théorie analytique de la chaleur, Paris, 1822.

Derived Dimensions. Many physical quantities have been introduced by mathematical definition. Velocity, for example, is defined as $v = \frac{ds}{dt}$, where s is the length of the path measured from a definite origin and t is the time. A possible expression for the dimension of velocity would be $[V]$. It is customary and convenient, however, to make use of the mathematical definition which is but the rule for the measurement of velocity, and to express the dimension in terms of the more familiar dimensions of length and time as a derived dimension $[V] = [L]/[T] = [L]\,[T]^{-1}$. (Read: velocity is of (+ 1) dimension in length and (− 1) dimension in time.) The use of mathematical definitions, leading to derived dimensions of a composite nature, reduces the number of symbols. Thus the measurement of volume, if scientifically conducted, gives $[Vol] = [L]^3$, or in words, "volume is of (+ 3) dimensions in length $[L]$."

Proportionality Constants of physics have, in general, *derived dimensions*, as they are defined by the corresponding physical equations. To assign a special dimension to a proportionality constant would mean to give it preference over a physical quantity and evidently would be illogical. This seemingly obvious fact has recently been recognized internationally, when the International Electrotechnical Commission (I.E.C.), after decades of discussion, at its meeting in 1930 at Oslo adopted the viewpoint that absolute magnetic permeability is a physical quantity with dimension and not a pure numeric.* For the absolute dielectric constant this view had been expressed much earlier, and for other proportionality constants this problem never had arisen.

Fundamental Dimensions. The more familiar dimensions used to express derived dimensions are referred to as fundamental dimensions. It is advantageous to use as few of these fundamental dimensions as possible, not because the physical relations become simpler or clearer, but merely as a matter of economy in symbols. In fact, any dimension can be chosen to be a fundamental dimension in a particular field and a derived dimension in some other field of physics. No fundamental dimension can be made a starting point of natural philosophy.

Dimensional Equations. Since a physical equation constitutes in fact two equations, one for the units and one for the numerics, one can disregard the numerical factors entirely and write the general units or dimensions only, arriving thus at a dimensional equation. For instance, the law of gravitation would read $[F] = [k]\,[M]^2\,[L]^{-2}$, using $[F]$, $[k]$, $[M]$, $[L]$ as dimensions for force, gravitation constant, mass, and length, respectively. From this dimensional equation a derived dimension can be obtained for any quantity involved. Conversely, dimensional equations are used to check the correctness of physical relations, if all dimensions can be made to cancel. Finally, the validity of dimensional equations leads to the method of dimensional analysis. (See Arts. 15 to 18.)

A Set of Fundamental Dimensions is any group of fundamental dimensions, convenient and useful to express all the physical quantities of a particular field in terms of derived dimensions. The number of fundamental dimensions to make a set may vary according to the field of application. Whether or not a set of fundamental dimensions can be used beyond the field for which it was originally intended will depend upon its suitability as a dimension system. (See next paragraph.) In no case should it be used where it can lead to confusion.

A set of fundamental dimensions is *incomplete* when the number of fundamental dimensions composing it is less than the number required for a dimension system. Incomplete sets of fundamental dimensions should not be used outside the very restricted field for which they are useful; they necessarily would lead to confusing relations.

A Dimension System is composed of the smallest number of fundamental dimensions which will form a consistent and complete set for a field of science. Since each relation between physical quantities can be split up into one relation of numerics and another one of dimensions (as general units), it is possible to combine all known relations of dimensions. In setting up these relations, all proportionality factors must be taken as physical quantities. If there are m independent relations known, $(m + p)$ dimensions may be involved, of which m dimensions can be expressed by any p "fundamental" dimensions chosen arbitrarily.

This set of p "fundamental" dimensions is then called a dimension system. From the theory of numbers, therefore, it is known that one generally has a choice of $\binom{m+p}{p}$ possible dimension systems. Thus, if $p = 3$, $m = 3$, then one has $\binom{6}{3} = 20$ different possibilities. A necessary condition, however, is that *each* independent relation involve at least $(p + 1)$ dimensions. If this is not the case, then the number of possible dimension systems is less, so that $\binom{m+p}{p}$ indicates the *upper* limit.

---

* A. E. Kennelly, *Trans. A.I.E.E.*, Vol. 50, p. 737, 1931.

Any dimension system chosen in the described manner is consistent, as well as correct, and never leads to ambiguity with respect to the expression of physical quantities. Complete dimension systems in mechanics must have three, in thermodynamics four,[*] and in electromagnetism four [†] fundamental dimensions. It seems, according to present knowledge, that five fundamental dimensions suffice for the entire range of physics, namely, the three fundamental dimensions of mechanics, an additional one for thermodynamics, and another additional one for electromagnetism.

All the known dimension systems use length $[L]$ and time $[T]$ as primary fundamental dimensions, adding various fundamental dimensions from the available physical quantities of the fields of physics. The choice of $[L]$ and $[T]$ reduces at once the maximum number of possible dimension systems to $\binom{m+p-2}{p-2}$.

Why Dimension Systems? Since the proper choice of units is the ultimate goal of any critical analysis of physical quantities the question may be asked: Why is it necessary to discuss dimension systems? The answer is that each physical quantity may be measured by an infinite variety of units but has only one dimension, within a given dimension system. The process of deciding upon the fundamental dimensions before fixing the units within the scope of the fundamental dimensions is, therefore, essentially a matter of economy and logic.

3. THE DIMENSION SYSTEMS OF MECHANICS

Three Fundamental Dimensions are necessary to form a complete mechanical dimension system. With length and time, $[L]$ and $[T]$, as a basis, only a single additional independent dimension is required. One can choose from mass $[M]$, force $[F]$, power $[P]$, energy $[E]$, gravitation constant $[k]$, and others. Only four alternatives have come into use. Table I shows the dimensional forms for the more important mechanical quantities in all four dimension systems.

Table I. Dimensions of Mechanical Quantities

Symbol (according to A.S.A.)	Quantity	Dynamical or Physical System	Gravitational or Technical System	Energetical System	Astrophysical System
l	Length	$[L]$	$[L]$	$[L]$	$[L]$
t	Time	$[T]$	$[T]$	$[T]$	$[T]$
v	Speed, velocity	$[L]\,[T]^{-1}$	$[L]\,[T]^{-1}$	$[L]\,[T]^{-1}$	$[L]\,[T]^{-1}$
m	Mass	$[M]$	$[F]\,[L]^{-1}\,[T]^2$	$[E]\,[L]^{-2}\,[T]^2$	$[L]^3\,[T]^{-2}\,[k]^{-1}$
f	Force	$[M]\,[L]\,[T]^{-2}$	$[F]$	$[E]\,[L]^{-1}$	$[L]^4\,[T]^{-4}\,[k]^{-1}$
p	Pressure	$[M]\,[L]^{-1}\,[T]^{-2}$	$[F]\,[L]^{-2}$	$[E]\,[L]^{-3}$	$[L]^2\,[T]^{-4}\,[k]^{-1}$
M	Momentum	$[M]\,[L]\,[T]^{-1}$	$[F]\,[T]$	$[E]\,[L]^{-1}\,[T]$	$[L]^4\,[T]^{-3}\,[k]^{-1}$
E	Energy	$[M]\,[L]^2\,[T]^{-2}$	$[F]\,[L]$	$[E]$	$[L]^5\,[T]^{-4}\,[k]^{-1}$
P	Power	$[M]\,[L]^2\,[T]^{-3}$	$[F]\,[L]\,[T]^{-1}$	$[E]\,[T]^{-1}$	$[L]^5\,[T]^{-5}\,[k]^{-1}$
T	Torque	$[M]\,[L]^2\,[T]^{-2}$	$[F]\,[L]$	$[E]$	$[L]^5\,[T]^{-4}\,[k]^{-1}$
k	Gravitation constant	$[M]^{-1}\,[L]^3\,[T]^{-2}$	$[F]^{-1}\,[L]^4\,[T]^{-4}$	$[E]^{-1}\,[L]^5\,[T]^{-4}$	$[k]$

The Dynamical or Physical Dimension System has as fundamental dimensions length, $[L]$, time $[T]$, and mass $[M]$. It is the most widely used system in physics and is often found even in engineering. The advantage is that any standard of mass can be preserved and copied with relative ease. Comparison of masses at various locations can be made with the ordinary balance; the local constant of gravity has no influence upon the result. This dimension system has often been referred to as the "absolute" system, but on account of inconsistent usage in the literature, it will generally be referred to herein as the physical dimension system.

The Gravitational or Technical Dimension System has as fundamental dimensions length $[L]$, time $[T]$, and force $[F]$. It is of wide use in all engineering branches, although often mixed with the physical dimension system. The advantage for the field of engineering is obvious, taking into account the prevalence of force, stress, and pressure computations.[*] All quantities related to force have particularly simple dimensional forms. The disadvantage is the dependence of the usual force measurements upon the local value of the constant of gravity.[†] Standards of force are expressed in terms of the weight of a standard mass and, therefore, are indirectly based upon the physical dimension system.

---

[*] For first reference to this fact, see Fourier's Théorie analytique de la chaleur, Paris, 1822.

[†] For first reference to this fact, see A. W. Rücker, *Proc. Phys. Soc. London*, 1888, Vol. 10, p. 37; *Phil. Mag.*, February, 1889, Vol. 27, p. 104.

The Energetical Dimension System [‡] has as fundamental dimensions length $[L]$, time $[T]$, and energy $[E]$. The dimensional forms of most of the important quantities are simpler, and this system should appeal to the scientist because of its close relation to the universal quantity energy. The system is not in use in mechanics; it has, however, gained prominence in heat. (See Art. 4 below.) Its disadvantage is the fact that no substantial standard of energy can be preserved with which results of measurements can readily be compared, as is the case with mass or force.

The Astrophysical Dimension System has as fundamental dimensions length $[L]$, time $[T]$, and the gravitational constant $[k]$. Here is a system which admits a proportionality constant to the rôle of a fundamental quantity with a fundamental dimension which is not advisable. The temptation exists to assign arbitrarily not a fundamental but a definite dimension and, in fact, astrophysics uses $k = 1$, which means that the numerical value of k is chosen as unity and its dimensions as zero. The dimensions of the other quantities in this special case are obtained from the last column in Table I if the factor with $[k]$ is left off on account of $[k] = [L]^0\,[T]^0 = 1$. This reduces the dimension system to an *incomplete set of dimensions* with very restricted use. To see this, choose in the physical system $m = 1$, as m is the proportionality constant in Newton's law $f = m \cdot a$, where a is the acceleration. Again, the dimensions for this special case would follow from the physical system by putting $[M] = 1$. For the gravitation constant this would yield $[k] = [L]^3\,[T]^{-2}$, the same dimension as results for mass in the incomplete astrophysical set of 2 fundamental dimensions; obviously this would invite confusion. One should avoid, therefore, the making of arbitrary assignments for dimensions considered to be fundamental because it will lead to contradictions.

4. THE DIMENSION SYSTEMS OF HEAT

Four Fundamental Dimensions are necessary to form a complete heat dimension system.[§] Obviously the simplest extension to four dimensions is to add a thermal fundamental dimension to the three fundamental dimensions of mechanics. As the additional thermal dimension that of temperature, $[\theta]$, has been chosen universally. Thus, three heat dimension systems are obtained according to the three first-named mechanical dimension systems from Table I. No extension of the astrophysical dimension system is known. In Table II are listed the dimensional forms for the more important thermal quantities in all three dimension systems.

Table II. Dimensions of Thermal Quantities

Symbol (according to A.S.A.)	Quantity	Thermophysical System	Thermotechnical System	Energetical System
	3 fundamental mechanical dimensions	$[L], [T], [M]$	$[L], [T], [F]$	$[L], [T], [E]$
θ	Temperature	$[\theta]$	$[\theta]$	$[\theta]$
H	Quantity of heat	$[M]\,[L]^2\,[T]^{-2}$	$[F]\,[L]$	$[E]$
c	Thermal capacity	$[L]^2\,[T]^{-2}\,[\theta]^{-1}$	$[L]^2\,[T]^{-2}\,[\theta]^{-1}$	$[L]^2\,[T]^{-2}\,[\theta]^{-1}$
k	Thermal conductivity	$[M]\,[L]\,[T]^{-3}\,[\theta]^{-1}$	$[F]\,[T]^{-1}\,[\theta]^{-1}$	$[E]\,[L]^{-1}\,[T]^{-1}\,[\theta]^{-1}$
h	Emissivity	$[M]\,[T]^{-3}\,[\theta]^{-1}$	$[F]\,[L]^{-1}\,[T]^{-1}\,[\theta]^{-1}$	$[E]\,[T]^{-1}\,[\theta]^{-1}$
s	Entropy	$[M]\,[L]^2\,[T]^{-2}\,[\theta]^{-1}$	$[F]\,[L]\,[\theta]^{-1}$	$[E]\,[\theta]^{-1}$

The Thermophysical Dimension System is the extension of the dynamical or physical mechanical dimension system by adding temperature $[\theta]$ as the fourth fundamental dimension.[*] It is the most widely used system and has all the advantages of the physical dimension system of mechanics. This system is sometimes reduced to an incomplete set of "absolute dimensions" by arbitrarily assuming temperature as a pure numeric. The dimensions in this case can be taken from Table II if $[\theta] = 1$ is introduced in the thermophysical system. The objections to such a procedure are obviously the same as in reducing the astrophysical system to less than the required number of fundamental dimensions, and the same argumentation can be used.

---

[*] See the new advocation by F. A. Brooks, *J. Engg. Educ.*, Vol. 25, p. 240, 1934.

[†] Wm. L. DeBaufre, *Proc. Soc. Promotion Engg. Educ.*, Vol. 28, p. 655, 1928.

[‡] W. Ostwald, *Berichte der Gesellschaft der Wissenschaften*, Leipsig, 1891, Vol. 43, p. 277.

[§] J. B. J. Fourier, Théorie analytique de la chaleur, Paris, 1822.

The Thermotechnical Dimension System is the extension of the gravitational or technical mechanical dimension system by adding temperature as the fourth fundamental dimension. Its use is rather restricted although it is the natural system to be used in engineering.

The Energetical Dimension System is the extension of the corresponding mechanical dimension system and has been proposed by W. Ostwald. It has not been used to any extent.

5. THE DIMENSION SYSTEMS OF ELECTROMAGNETISM

Four Fundamental Dimensions are necessary to form a complete dimension system for the field of electromagnetism exclusive of thermal phenomena.* Obviously the simplest extension to four dimensions is to add an electromagnetic fundamental dimension to the three fundamental dimensions of mechanics. In general, one can choose from among all electromagnetic quantities; in particular, one would probably prefer to choose the dimension of a quantity which comes nearest to the fundamental concept of electricity. Length and time, forming the fundamental background of sensual perception, and mass or force as the fundamental representative of mechanical inertia, demand a companion of equal basic character.

There are three fundamental electromagnetic experiments which involve all the basic quantities of electromagnetism. The two independent experimental laws forming the base of electrostatics on one side and electrodynamics on the other side are Coulomb's law

$$f_e = k_e \frac{Q_1 Q_2}{r^2} \tag{1}$$

and Ampère's law

$$f_m = k_m \frac{I_1 I_2}{r} \cdot l \tag{2}$$

expressing the force actions between two electric charges Q_1 and Q_2 at rest, and between two electric currents I_1 and I_2, respectively. k_e and k_m are the two proportionality factors, r is the center distance, and l the homogeneous length of the two conductors carrying current. As current is merely displacement of charge, the additional relation $I = \frac{dQ}{dt}$ must hold, which is the expression of a basic concept.

The third experimental law which connects the purely electric with the magnetic phenomena is Faraday's law of induction

$$V = -k_i \frac{d\phi}{dt} \tag{3}$$

where V is the induced voltage (emf), ϕ the magnetic flux linked with the conductor in which V is produced, and k_i another proportionality factor.

The variety of electromagnetic quantities leads one to expect a corresponding variety of dimension systems. In Table III are shown the dimensions of the more important electromagnetic quantities in eight different dimension systems of varying prominence and varying logical foundation.

The Natural Electrical Dimension Systems

The Electrophysical Dimension System † is the extension of the dynamical or physical mechanical dimension system by adding electric charge $[Q]$ as the fourth fundamental dimension. (See column 1 of Table III.)

The Electrotechnical Dimension System † is the extension of the gravitational or technical mechanical dimension system by adding electric charge $[Q]$ as the fourth fundamental dimension. (See column 2 of Table III.)

Both systems are the natural extensions of existing mechanical systems and use the basic concept of quantity of electricity as the additional fundamental dimension. Although the electron is recognized occasionally as a truly elemental quantity,‡ the tendency has prevailed to choose resistance as a fundamental dimension since it is thought to be more readily reproduced. Newer investigations show the resistance of a metal to be a very

		The "Fractional" Systems	

complicated function of the surrounding conditions and a function of the density of free electrons, which points in the direction of the above natural dimension systems as more satisfactory than systems using electrical resistance as a fundamental quantity.

The Definitive Dimension System * is the extension of an energetical mechanical dimension system (using length, time, and power) by adding electric charge $[Q]$ as the fourth fundamental dimension. (See column 3 of Table III.) As there are no standards available for power, this system is indirectly based upon the physical system. The choice of power as a fundamental quantity was obviously made in view of the extensive use of the watt as a unit in all fields of physics.

The Fractional Electrical Dimension Systems

The Electrostatic Dimension System (ES-System) is the extension of the dynamical or physical mechanical dimension system, by adding the proportionality constant $[k_e]$ as the fourth fundamental dimension. Notwithstanding the fact that a proportionality constant has been advanced to a fundamental dimension, all the magnetic quantities are dependent on some power of $k_e = \dfrac{1}{4\pi\Delta}$, which seems quite illogical. The most extensive use of this dimension system as a preferred one has been made by E. Bennett.† (See column 6 of Table III.)

The Electromagnetic Dimension System (EM-System) is the extension of the dynamical or physical mechanical dimension system, by adding the proportionality constant $[k_m]$ as the fourth fundamental dimension. Again a proportionality constant has been advanced to the rank of a fundamental dimension and all the electric quantities are dependent upon some power of $k_m = \dfrac{1}{2\pi}\cdot\Pi$, which seems quite illogical. (See column 7 of Table III.)

Both systems are complete dimension systems as they are based upon four fundamental dimensions. The emphasis placed upon the proportionality factor seems out of place, and the fact alone, that all the electromagnetic quantities appear as derived fractional dimensions, should indicate that better systems could be found. It is further to be noted that both systems belong in the same class of dynamical or physical dimension systems and, therefore, do not constitute a true alternative. Any preference as to the first or second system introduces a dissymmetry into the dimensional expressions and stresses a particular field of electromagnetism which cannot be the intention of any comprehensive dimension system.

† E. Bennett, A digest of the relations between the electrical units, *Bull. Univ. Wisconsin*, No. 880, 1917

The Symmetrical Dimension System. Taking cognizance of the fact that the two proportionality constants k_e and k_m differ in their dimensions by the factor $[L]^2[T]^{-2}$, which happens to be the square of the dimension of a velocity, the relation

$$[k_e] = [k_m][L]^2[T]^{-2}$$

can be used to express either in the electrostatic system all the magnetic quantities in dimensions of $[k_m]$ rather than $[k_e]$, or in the electromagnetic system all the electric quantities in dimensions of $[k_e]$ rather than $[k_m]$. The last column in Table III shows the resulting hybrid system which exhibits a remarkable symmetry in the principal electric and magnetic quantities as far as the three mechanical dimensions are concerned; it might be referred to as the *generalized Gaussian dimension system.* Obviously, in all equations combining electric and magnetic quantities, an arbitrary factor must be introduced in order to balance the dimensions on both sides and this factor must have the characteristics of a velocity or some power of it. In fact, this velocity was found to be of the same value as the velocity of light in free space and this was taken as an indication of a very fundamental principle. (It is not conceivable, however, what rôle the velocity of light for free space should play in ordinary physical phenomena.) In this dimension system, then, the factor c, denoting the velocity of light in free space, appears repeatedly, as for example in the induction law $V = \frac{1}{c}\frac{d\phi}{dt}$, where the induced voltage (emf) is measured electrostatically and the magnetic flux is measured electromagnetically. (See column 8 of Table III.)

The So-called Absolute Electrical Dimension Systems

The original use of the word "absolute" in connection with electrical measurements goes back to the report of the Committee on Electrical Standards, British Association for the Advancement of Science, 1863, which states:

> "The word "absolute" in the present sense is used as opposed to the word "relative" and by no means implies that the measurement is accurately made or that the unit implied is of perfect construction; in other words, it does not mean that the measurement or units are absolutely correct but only that the measurement instead of being a simple comparison with an arbitrary standard of the same kind as that measured is made by reference to certain fundamental units of another kind treated as postulates."

As the fundamental units, length, mass, and time, were commonly used, any measurement made in terms of these specific quantities is now customarily called an "absolute" measurement. To indicate the injudicious use of the word absolute it is prefixed with "so-called" in this section.

In connection with the use of dimensions it also became customary to call the dynamical or physical dimension system the "absolute" dimension systems. Assigning, then, arbitrarily, zero dimension to the proportionality factors occurring in the basic experimental laws of electromagnetism, the fractional electrical dimension systems (see Table III) reduce to the so-called "absolute" dimension systems. The additional arbitrary disposal of the dimension of the proportionality constant or constants thus leads within electromagnetism to an incomplete set of fundamental dimensions. According to the three fractional dimension systems three different sets of dimensions for the electromagnetic quantities suggest themselves and have been used.

The So-called Absolute Electrostatic Dimension System is the electrically incomplete set of the three fundamental dimensions of the physical mechanical dimension system derived from the fractional electrostatic dimension system by arbitrarily assuming k_e as purely numeric. The dimensions for this incomplete set are obtained from Table III, column 6, by introducing $[k_e] = 1$.

The So-called Absolute Electromagnetic Dimension System is the electrically incomplete set of the three fundamental dimensions of the physical mechanical dimension system derived from the fractional electromagnetic dimension system by arbitrarily assuming k_m as purely numeric. The dimensions for this incomplete set are obtained from Table III, column 7, by introducing $[k_m] = 1$.

The Gaussian or So-called Absolute Symmetrical Dimension System is the electrically incomplete set of the three fundamental dimensions of the physical mechanical dimension system obtained from a peculiar combination of the fractional electrostatic and electromagnetic dimension systems as shown in Table III, column 8, by specifying $[k_e] = [k_m] = 1$, i.e., defining both proportionality constants as pure numbers. The remarkable result is that all the electric quantities, including the current, are in the electrostatic dimension system, and the magnetic quantities are in the electromagnetic system. This Gaussian set of dimensions has been almost exclusively used in theoretical physics * on the basis that the symmetry in the dimensional expressions of electric and magnetic quantities facilitates the teaching of electromagnetism. There is, however, no definite agreement on the dimension of electric current, although most authors prefer the expression following from the electrostatic dimension system.

On the Use of the So-called Absolute Electrical Dimension Systems. Probably no other single question has raised so many discussions as the question of the "proper" dimensions of the electromagnetic quantities. As has been stated (See Art. 2) the chief advantages of using the concept of physical dimensions are;

1. The number of fundamental dimensions is the same as the number of fundamental units.
2. Physical equations can be checked by dimensional homogeneity.
3. New physical relations can be obtained by the use of dimensional analysis (See Art. 17).

It is obviously desirable to define fundamental and derived dimensions in such a way that the least amount of confusion arises and that easy communication of research is possible. The definition of complete dimension systems in electromagnetism requires from this point of view four fundamental dimensions as has been pointed out repeatedly in the past.† The arbitrary suppression of the dimension of a proportionality constant, as done in the case of the so-called "absolute" systems, leads to confusion in dimensional analysis,‡ and makes difficult the checking of the dimensional homogeneity of equations.

Recent discussions show a definite tendency towards accepting this fact and particularly to choose electric charge as the fourth fundamental dimension, leading to the electrophysical dimension system (see Table III, column (1)), in which all dimensional expressions become rather simple.§

The S.U.N. (Symbols, Units and Nomenclature) Commission of the International Union of Pure and Applied Physics in a letter by R. T. Glasebrook (Nov. 30, 1935) ¶ concedes, that "On a modern 'Maxwell' theory of electricity the permeability of space, . . . is assumed to be a quantity having dimensions."

Since physicists have generally reduced the problem of choosing three or four fundamental dimensions in electromagnetism to the question whether magnetising force H and magnetic flux density B have equal or different dimensions,‖ the concession that permeability is a physical quantity with dimension is equivalent to a rejection of the so-called "absolute" dimension systems in electromagnetism. The same report, however, stresses the fact that ". . . the S.U.N. Commission desires to take this opportunity of placing on record their recognition of the fact there are important electrical theories supported by a number of physicists in accordance with which . . ." the product of absolute permeability and absolute dielectric constant is a pure number. This is equivalent to accepting the use of the Gaussian system which is still preferred by many of the theoretical physicists.**

It may be emphasized, that the question of the proper number of fundamental dimensions or units is entirely divorced from the other question of the definition of electromagnetic units. It is well possible to retain the so-called "absolute" electrostatic units as values with dimensions following from any one of the complete dimension systems based upon so-called absolute measurements.

Various "Practical" Dimension Systems

The fractional dimension systems were the first ones used and may duly be called the "classical" dimension systems as they had been proposed by the classical authors in the art. Their value in promoting first quantitative measurements of electromagnetic quantities cannot be doubted. Yet, the inconvenience in using fractional dimensions and the fact that proportionality factors were given such unwarranted prominence led to various proposals of so-called practical dimension systems. The aim of these systems is simplicity, stress upon fundamental concepts, and practicability.

The So-called Practical Dimension System has as fundamental dimensions length $[L]$, time $[T]$, current $[I]$, and resistance $[R]$, based upon the fact that convenient standards are available for the two electrical quantities. The system is used rather extensively in the engineering literature,* although not always explicitly stated. The fact that two fundamental electrical dimensions are chosen renders it difficult to combine it with the known mechanical dimension systems, and this is an objectionable feature. (See column 4 of Table III.)

The Energetical Dimension System is the extension of the mechanical dimension system with the same name by adding voltage $[V]$ as a fourth fundamental dimension. It had been proposed by W. Ostwald † but never has been used in the literature. (See column 5 of Table III.)

The disadvantage of all the "practical" systems is their departure from existing mechanical dimension systems from which, however, they cannot be entirely dissociated, since the fundamental standards of energy or power must be based upon the standard of mass in order to be internationally available.

UNIT SYSTEMS

6. UNITS AND UNIT SYSTEMS

Definition of Units. A physical quantity can be measured only by comparison with a like quantity. Defining a distinct amount of a physical quantity as "unit," i.e., as reference value, any physical quantity of the same kind can be compared with it, and its value is then stated in terms of a ratio number and the unit used. Obviously there is an infinity of possibilities for choosing a unit of a single physical quantity. *All the possible units* of the same physical quantity *must be related by purely numerical factors* which are used as the expressions for direct comparison. (See also Art. 1.)

Units and Dimensions. The general unit of a physical quantity is defined as its *dimension.* (See Art. 2.) There can be only one dimension for each physical quantity if the units are to be related by numerical factors only; but there are as many dimensions as there are physical quantities. Obviously, the concept of dimension systems, as outlined (see Art. 2), facilitates easy orientation and permits the use of a few fundamental dimensions to express all physical quantities in general units. Likewise, the concept of the fundamental unit permits the expression of all other units in terms of the fundamental units. However, whereas dimensional relations are essentially exponential equations, unit relations necessarily include numerical values in their equations.

Unit Systems. On the basis of a proper dimension system a unit system can be developed by choosing, for each fundamental dimension of the system, a specific unit, desirably related to a fundamental standard or standards. These units are called *fundamental units*; the respective physical quantities, fundamental quantities. Their number must be the same as the number of fundamental dimensions in the respective dimension system in order to constitute a complete unit system. All other physical quantities are then expressible in terms of the fundamental quantities and their units. Obviously there can be an infinity of unit systems for each complete dimension system; but for international understanding it is desirable to limit the usage to a few unit systems.

Systematic Units are all systematically derived units within a unit system, obtained by replacing the general units, as indicated in the derived dimension of the quantity, by the fundamental units of the system. Thus, in a m-kg-sec physical mechanical unit system, the systematic unit of power with the dimension $[M]\,[L]^2\,[T]^{-3}$ will be 1 kg m^2 sec^{-3}, which is known as 1 watt. The unit relations between systematic units are, therefore, unitary, i.e., do not involve numerical factors. Unit systems with only systematically derived units are the ultimate goal in any branch of physics; they are difficult to obtain because the units should all be of convenient practical size.

---

* Mie, G., Lehrbuch der Elektrizität und des Magnetismus, Stuttgart, 1910; Karapetoff, V., The Electric Circuit, The Magnetic Circuit, New York, 1910.

† W. Ostwald, see footnote, p. 3-06.

Derived Units. All units which are not fundamental may be called derived units. Systematic units form the most prominent group of derived units, although all mixed units would come into this same category. Derived units can be the same for several unit systems if the defining fundamental units are the same. In many cases, where systematically derived units are inconvenient, mixed units will be used. In the m-kg-sec system "charge density" would have the systematic unit "coulomb per square meter," whereas more convenient is the unit "microcoulomb per square centimeter," a multiple of a mixed unit.

Units and Physical Equations. The form of physical equations depends upon the units employed for the various physical quantities. In general, the simplest forms will result when units of the same system are used exclusively. Two different types are, therefore, distinguished.

Systematic Physical Equations use only systematic units for all physical quantities involved. These equations are independent of the specific unit system applied, their form is the simplest obtainable without numerical factors, and their use should be preferred in all general texts. If a definite dimension system is chosen, it will, in conjunction with the proper number of fundamental units, form a sufficient basis for the correct interpretation of the general equations, written in systematic form.

Non-systematic or Hybrid Physical Equations use units from different unit systems or various multiples of units of the same system. These equations involve additional numerical factors (and numerical factors only, if all incomplete dimension sets are excluded). In all non-systematic equations it is imperative to state the units to be used for the various quantities in order to avoid confusion and misunderstandings. Many examples of non-systematic equations can be found in electromagnetism, where hybrid relations are very common. (See Art. 9.)

Comprehensive Unit Systems are composed of five fundamental units to cover the whole field of physics. The difficulties in designing a comprehensive unit system come from the restriction that all the systematic units should be convenient and practical or at least be made so by simple powers of 10. Many attempts have been made to reach international agreement on a single comprehensive system, but thus far none has succeeded. The advantage of such a system is obvious, since all physical equations could be used in their systematic form, introducing all the physical quantities in convenient practical values.

So-called Absolute Unit Systems. During the middle of the nineteenth century it became customary to refer to measurements in terms of the centimeter-gram-second mechanical unit system as "absolute" measurements, and the cgs system, as adopted and recommended by the British Association for the Advancement of Science in 1873, was called the "absolute" unit system. This designation is entirely unwarranted, as no system can claim "absoluteness." The attempts to reduce the fractional electrical dimension systems to the three so-called absolute mechanical dimensions, and then to use the absolute mechanical units in electrical measurements, have resulted in confusion and inconsistencies. It is inadvisable to use less than four fundamental units in electromagnetism, and for this reason, the so-called absolute unit systems will not be considered here at all. The complete unit systems resulting from the fractional dimension systems, which sometimes are called "complete absolute" systems because of their complete set of fundamental dimensions, will be called here "*theoretical*" *unit systems*.*

The Metric Unit Systems are based upon the international metric standards, namely: the meter and the kilogram, or any decimal multiples thereof. Only the metric systems enter in general into the discussion of comprehensive unit systems.

Metric Multiples and Metric Style. Prefixes used to indicate ***multiples*** and ***submultiples*** of various metric units are shown in the following table:

micro = 10^{-6}
milli = 10^{-3}
centi = 10^{-2}
deci = 10^{-1}

deka = 10^{1}
hecto = 10^{2}
kilo = 10^{3}
myria = 10^{4}
mega = 10^{6}

Example. One centimeter = 10^{-2} meter; one kiloliter = 10^{3} liters; one milligram = 10^{-3} gram. Metric numbers are written with the decimal point (.) at the right of the figures denoting the unit; thus the expression, 15 meters 3 centimeters, is written 15.03 meters.

---

* G. Mie, "Elektrodynamik," Handbuch der experimental Physik, Vol. 11, 1932.

When metric numbers are expressed by figures, the part of the expression at the left of the decimal point is read as the number of the unit, and the part at the right, if any, as a number of the lowest denomination indicated, or as a decimal part of the unit; thus, 46.525 meters is read 46 meters and 525 millimeters, or 46 and 525 thousandths meters.

The English Unit Systems are based upon the English standards, namely: the yard and the pound, or any multiples thereof. See Units and Standards, p. 3–21.

7. THE METRIC UNIT SYSTEMS OF MECHANICS AND HEAT

The Distinctly Mechanical Unit Systems

There are several mechanical unit systems in use, which are shown in Table I, with their systematic units (the fundamental units are printed bold face) for the most important quantities. It is significant that only one technical and three physical systems have been developed. The variety of the unit systems is not due to variety in dimension systems, but rather to the choice of various multiples of the same unit quantity.

Table I. The Metric Unit Systems of Mechanics

Unit System Author Year Basic Dimension System	CGS France 1799 Physical (Dynamical)	Technical Technical (Gravitational)	MKS G. Giorgi 1902 Physical (Dynamical)	MTS France 1913 Physical (Dynamical)
Quantity	①	②	③	④
Length....................	**cm**	**m**	**m**	**m**
Time....................	**sec**	**sec**	**sec**	**sec**
Mass....................	**g**	$\frac{1}{9.81}$ kg mass	**kg**	**ton**
Force....................	dyne	**kg force**	joules/m	sthène = 10^8 dynes
Power....................	erg/sec	$\frac{1}{9.81}$ watt	watt	kilowatt
Energy....................	erg	kg force-m	joule	kilojoule

The CGS (Centimeter-gram-second) System of Units is a dynamical system of units and is based upon the centimeter, gram-mass, and second as fundamental units (column 1 of Table I). It was first proposed in 1795, and adopted in France by the French statute of Dec. 10, 1799. The standard to which the length unit refers is the prototype meter (see standards); the standard to which the gram has reference is the prototype mass of the kilogram (see standards). This system was endorsed and recommended for use by the British Association for the Advancement of Science in 1863 and since then has been most widely used internationally, in all sciences. Frequent objections to the cgs system are the fact that the actual standards are for multiples of these fundamental units and not for the units themselves; that the derived units for force and energy are inconveniently small for practical purposes; and that it does not fit with the practical electrical units to form a comprehensive unit system.

The MKS (Meter-kilogram-second) System of Units is a dynamical system of units and is based upon the meter, kilogram-mass, and second (column 3 of Table I). It was proposed by G. Giorgi * (1902) and adopted by the International Electrotechnical Commission at Paris, 1935. Its convenience lies in the fact that it is based upon the actual standards, as preserved in Paris, the meter and the kilogram-mass prototype. The disadvantage of large magnitudes for densities and gradients may be not serious, depending on general usage. The density of water is 10^3 kg per cu meter, and this is rather inconvenient in many practical computations.

The MTS (Meter-ton-second) System of Units is a dynamical system of units and is based upon the meter, metric ton (mass), and second (column 4 of Table I). It was proposed in 1913 † and legalized in France in 1919. The units are in some respects better adapted to practical use than those in the cgs system; but it is not suitable for extension into a comprehensive system or as a unit system for physics. Its main advantage is the fact that the density of water under normalized conditions becomes 1 ton per cu meter and thus has the same numerical value as in the cgs system (where it was 1 g per cu cm).

---

* G. Giorgi, *Elec. World*, Vol. 40, pp. 355, 368, 1902.

† See A. E. Kennelly, *Proc. Soc. Prom. Engg. Educ.*, Vol. 19, p. 229, 1928.

The "Technical" System of Units is a gravitational system of units and is based upon the meter, kilogram (force), and second as fundamental units (column 2 of Table I). Since the standard of force is defined as the weight of the prototype standard mass of the kilogram, the fundamental unit of force is variable. International agreement determined a standard value of the constant of gravity (see Units and Standards) which for all practical measurements is little different from the local value at the point of measurement. As the system is decidedly a technical system of units, widely used by engineers and the industry, this disadvantage is not serious at all. The advantages in practical design work and in numerical computations more than justify the use of this unit system, yielding very simple dimensional formulas and self-explanatory derived unit names.

The Thermal Unit Systems

Any mechanical unit system supplemented by temperature as a fourth fundamental unit constitutes a proper thermal unit system. Table II gives a summary of the units most frequently used and their coordination in the various thermal unit systems.

Table II. The Thermal Units Most Commonly Used

Quantity	Caloric Unit System ①	CGS Thermal Unit System ②	MKS Thermal Unit System ③
Fundamental			
Length	cm	cm	m
Time	sec	sec	sec
Mass	(4.184 gram-seven)*	g	kg
Temperature	° C	° C	° C
Energy	cal	(erg)	(joule)
Derived			
Thermal conductivity	cal/sec ° C cm	erg/sec ° C cm	watt/° C m
Thermal capacity of body	cal/° C	erg/° C	joule/° C
Thermal capacity of substance	cal/sec ° C g	erg/sec ° C g	watt/° C kg
Emissivity	cal/sec ° C cm^2	erg/sec ° C cm^2	watt/° C m^2
Entropy	cal/° C	erg/° C	joule/° C

The Caloric Unit System is based on the centimeter, second, calorie, and degree centigrade (column 1 of Table II). The peculiar definition of the unit of energy produces inconvenient systematic units of mass and force. For this reason a practical modification is widely used, by employing the non-systematic units of gram and dyne in computations. It is with this system that Fourier founded the theory of dimensions.† The most commonly used quantities and their units are shown in Table II.

The CGS Thermal Unit System is the extension of the cgs mechanical unit system (column 2, Table II) by the addition of the metric unit of temperature (degree centigrade). Although a dynamical or physical system, it is widely used in heat engineering on account of the erg as the unit of energy which provides a close link to the watt and the practical electrical unit systems. The most commonly used quantities and their units are shown in Table II.

The MKS Thermal Unit System is the extension of the mks mechanical unit system (column 3, Table II) by the addition of the metric unit of temperature (degree centigrade). It is widely used in general engineering on account of the convenient magnitudes of its fundamental units. The most commonly used quantities and their units are shown in Table II.

8. THE METRIC COMPREHENSIVE UNIT SYSTEMS

The comprehensive unit systems are composed of five fundamental units in order to cover the whole field of physics. There are *eleven* comprehensive unit systems in use, each one with a different name; in addition, there is the QES system, which was used by J. C. Maxwell to explain the " practical " units in terms of the theoretical definitions. In Table III are shown all twelve unit systems with their authors, the year of proposal or first use, and the dimension system upon which the unit system was based (the fundamental units are bold-face type).

It can be seen that *nine* of the systems are *physical* unit systems; only one a technical system and two systems belong in the so-called "practical" class. Most of the variety can, therefore, be accounted for by slight changes in the choice of the multiple of the

mass unit or by the choice of the supplementary electrical unit. Unfortunately, many of the physical texts still use Maxwell's unit systems or the rationalized systems, so that the whole variety (except the QES system) actually can be found in the present-day literature.

Another grouping, according to the type of the dimension system (see Art. 5), shows six "fractional," three so-called practical, and three "natural" systems. Since all the quantities are given with their systematical units, it is easily seen that the natural systems (with charge as fundamental quantity) represent the most convenient arrays of units for practical use.

The "Theoretical" Comprehensive Unit Systems

All the "theoretical" dimension systems are characterized by the fact that they use as fundamental electrical dimension either k_e or k_m, the proportionality constants in the two fundamental experimental laws. In the "theoretical" unit systems these same factors are then assumed to have the magnitude unity, so that in combination with the three fundamental mechanical units all the electromagnetic units can be derived.

The CGS Electrostatic Unit System is the extension of the cgs mechanical system of units into a comprehensive system by adding the metric unit of temperature, degree centigrade, and defining the absolute dielectric constant (permittivity) as 1 statfarad per centimeter (see Units and Standards); see column 2, Table III. It is a dynamical unit system and was introduced by J. C. Maxwell.* It is frequently used in the field of electrostatics, especially in the form of an incomplete set of dimensions as a so-called absolute system which is obtained if the dimension of the dielectric constant is arbitrarily taken as zero, so that capacity will appear with the dimension "centimeter." In all texts employing the so-called absolute units and giving capacity in "centimeters," replace this unit by statfarad. The most commonly used quantities and their units in the complete cgs electrostatic system are listed in Table IV, first column. The unit system has many non-systematic units, and so the electromagnetic equations contain numerical factors (Art. 9).

The CGS Electromagnetic Unit System is the extension of the cgs mechanical system of units into a comprehensive system by adding the metric unit of temperature (degree centigrade) and defining the absolute magnetic permeability as 1 abhenry per centimeter (see Units and Standards); see column 3, Table III. It is a dynamical unit system and was introduced by J. C. Maxwell,* as an alternative to the cgs electrostatic unit system. It is frequently used in the treatment of magnetic fields, especially in the form of an incomplete set of dimensions as a so-called absolute system, which is obtained if the dimension of the permeability is arbitrarily taken as zero, so that inductance will appear with the dimension "centimeter." In all texts employing so-called absolute units and giving inductance in "centimeters," replace this unit by abhenry. The most commonly used quantities and their units in the complete cgs electromagnetic system are listed in Table IV, second column. The system has many non-systematic units, and so the electromagnetic equations contain numerical factors (Art. 9).

The CGS Symmetric Unit System is a combination of the cgs electrostatic and the cgs electromagnetic unit systems in such manner that all the electrostatic and electric current quantities appear in electrostatic units and all the magnetic quantities in electromagnetic units. In order to achieve this result a new factor was introduced into the fundamental electrical equations (see Art. 9), so that both the dielectric constant and the permeability could be defined arbitrarily as one statfarad per centimeter and one abhenry per centimeter, respectively. In this way symmetry in the expression was obtained. The new factor introduced was found to have the same numerical value as the velocity of light †; however, its identification with the velocity of light is not possible (see "Absolute " Dimension Systems, Art. 5). This symmetric system is frequently used in European publications, mostly in the form of an incomplete set of fundamental dimensions as the so-called absolute Gaussian system, which is obtained if the dimensions of both the absolute dielectric constant and the absolute permeability are taken as zero. Capacitance as well as inductance will then appear with the dimension "centimeter," which should be replaced properly by statfarad and abhenry, respectively. The "absolute" modification was the one used by C. F. Gauss and W. Weber in the classical investigations on measurements of electromagnetic quantities. The system has many non-systematic units, and so the electromagnetic equations contain numerical factors. (See Art. 9.)

The Rationalized CGS Electromagnetic Unit System was introduced and vigorously defended by O. Heaviside,‡ whereas *the rationalized cgs symmetric (Gaussian) unit system* was used by H. A. Lorentz.§ Both systems are identical with the unrationalized systems of the same name but use a factor 4π in Coulomb's and Ampère's laws instead of in the less logical positions where the classical theory had used them. As a result the electromagnetic field equations take on very simple forms. (See Art. 9.) All the units of the rationalized systems bear ratios of $\sqrt{4\pi}$ or multiples thereof to the cgs units of the same systems as shown in Table IV. This fact has prohibited their use in practical computations, although they are often found in modern treatises on electromagnetism, particularly in the English language. Where the rationalized systems have degenerated into so-called absolute systems the same considerations apply as in the unrationalized cgs systems.

NOTES: 1. For relations between the various units see conversion tables.

2. The unit names are used according to the latest decisions of the I. E. C. (International Electrotechnical Commission), at Paris, 1932.

The QES System of Units. J. C. Maxwell * has shown that, on the basis of the centimeter, gram, and second, a unit system can be devised in which again the absolute dielectric constant has the value 1 statfarad per centimeter but in which all the other electromagnetic quantities appear in the units of the so-called practical system. Since the cgs units and the practical units are in general related by high powers of 10 (see conversion tables), the fundamental unit of length should be 10^9 cm (or a quadrant), and that of mass should be 10^{-11} gram (eleventh-gram), whereas the second must be preserved as the unit of time. This system never has been used; it is not logical to let a proportionality factor retain unity as its magnitude and accept impractical fundamental units.

---

* J. C. Maxwell, Electricity and Magnetism, London, 1881.

The Various Practical Comprehensive Unit Systems

All the practical unit systems use the international units (for details see chapter on Units and Standards) for the electromagnetic quantities. Differences are only with respect to the designation of fundamental units which in turn bears upon the standards to be used. Table IV gives the most commonly used quantities with their practical units; distinction is made between the meter and the centimeter as fundamental units of length.

The So-called Practical Unit System is based upon the centimeter and second as fundamental mechanical units, adding the metric unit of temperature (degree centigrade) and two electrical units, the ampere and ohm. It was independently introduced into the literature by V. Karapetoff * and G. Mie.† The fact that two electrical units are considered fundamental would require primary standards for these and remove the prototype kilogram mass as a primary standard. The removal of the kilogram mass is perhaps the outstanding objection to the system. Another disadvantage is that the systematic unit of mass is rather large.

The MKS System of Units is a dynamical or physical system and is based upon the meter, kilogram (mass), second, degree centigrade, and ohm as fundamental units. (See column 6, Table III.) This system was accepted internationally in June, 1935, by the I.E.C. without, however, the originally proposed fundamental electrical quantity ohm; it is called the Giorgi-MKS system after its proponent.‡ Instead of the ohm the suggestion was made to use the value of the absolute permeability as 10^{-7} henry per meter which would render this system a strictly comprehensive unit system. A disadvantage of this system is the large value for the density of water, namely 10^3 kg per cu m; the advantage is the close relationship to the original standards of mechanical units.

The CGSS System of Units is a dynamical or physical system based upon the mechanical units centimeter, gram-seven (10^7 gram), and second, the metric unit of temperature (degree centigrade), and the definition of the absolute dielectric constant as a fundamental constant (column 9, Table III). The system had been proposed by E. Bennett § in 1917 and is essentially derived from the electrostatic unit system, replacing the unit statfarad per centimeter by farad per centimeter for the dielectric constant. It, therefore, has the same disadvantage of unsymmetry as Maxwell's unit system and in addition calls for a rather large unit for mass in order to bring in the electrical practical units. This system is not widely used.

The Natural Comprehensive Unit Systems

The unit systems based upon the electric charge as fundamental electrical dimension are here called "natural" comprehensive unit systems (see also Natural Dimension Systems) in order to emphasize the contradistinction from the "theoretical" unit systems based upon quantities of secondary importance.

The Electrophysical Unit System is the extension of the mechanical cgs system into a comprehensive unit system by adding the metric unit of temperature (degree centigrade) and the electromagnetic unit of charge as fundamental units (column 11, Table III). It is practically identical with the electromagnetic system of Maxwell except that it is based upon the definition of the electric charge and leaves the values of the dielectric constant and permeability adjustable with the progress of measurements pertaining to the velocity of light. Although seemingly a minor point, this is of practical importance with respect to standards. This system has been proposed recently ¶ as an alternative to the electrotechnical system in order to preserve the internationally adopted electromagnetic units which have been used very frequently.

The Electrotechnical Unit System is the extension of the mechanical "technical" system into a comprehensive unit system || by adding the metric unit of temperature (degree centigrade) and the coulomb as fundamental units (column 10, Table III). The change from kilogram force as unit of force to joule per meter makes this system identical with the kms system in regard to units, but leaves it as a gravitational system which is of distinct advantage in engineering. This system has been proposed recently ¶ as an alternative to the electrophysical unit system.

The " Definitive " System of Units is an energetical system based upon the meter, second, watt, degree centigrade, and coulomb as fundamental units (column 12, Table III). It combines the advantage of the mks system, the convenient relation between mechanical

Absolute magnetic permeability	$B = \Pi\cdot H$	$\Pi = \Pi_0\cdot\mu$ $\Pi_0 =$	$\frac{1}{V^2}$ stathenry/cm	1 abhenry/cm	1 abhenry/cm	1 abhenry/cm	1 abhenry/cm	$4\pi\times10^{-9}$ henry/cm
Electrostatic induction	div $D = \alpha\cdot\rho$	$\alpha =$	4π	4π	4π	1	1	1
Magnetic circuit	$\oint H_s\cdot ds = \beta\cdot I$	$\beta =$	4π	4π	$\frac{4\pi}{V}$	1	$\frac{1}{V}$	1
Faraday's induction law	curl $E = -\lambda\cdot\frac{\partial B}{\partial t}$ $\left(\text{EMF} = -\lambda\cdot\frac{\partial\Phi}{\partial t}\right)$	$\lambda =$	1	1	$\frac{1}{V}$	1	$\frac{1}{V}$	1
Poynting vector	$S = s\cdot(E\times H)$	$s =$	$\frac{1}{4\pi}$	$\frac{1}{4\pi}$	$\frac{V}{4\pi}$	1	V	1

Other relations: Conservation of electricity $I = \frac{dQ}{dt}$.

First Maxwell's relation curl $H = \beta\cdot G + \frac{\beta}{\alpha}\cdot\frac{\partial D}{\partial t}$.

Specific electric field energy $W_e = s\cdot\frac{\beta}{\alpha}\cdot\frac{1}{2}ED$.

Specific magnetic field energy $W_m = s\cdot\lambda\cdot{}^1/_2\,HB$.

Velocity of propagation in free space $c^2 = \frac{\alpha}{\beta\lambda}\cdot\frac{1}{\Delta_0\Pi_0}$.

NOTES: 1. The units employed for the electromagnetic quantities are those from Table IV for each system.

2. If units of various systems are used in one equation, the unit relations can be used for transformations, as for example:

$$\oint H\cdot\overline{ds} = 4\pi\cdot I \text{ if } H \text{ is in oersteds, and } I \text{ in abamperes.}$$
$$= \frac{4\pi}{10}\cdot I \text{ if } H \text{ is in oersteds, and } I \text{ in amperes.}$$

3. The factor V (or a multiple thereof) is a pure number, identical with the magnitude of the velocity of light in free space if expressed in centimeters per second.

and electrical practical units, with the selection of charge as a fundamental unit. It has the disadvantage of discarding mass as a primary unit and replacing it by the watt for which no convenient standard is known. This system has been proposed only recently by G. A. Campbell * and aims at a unique, internationally acceptable, practical unit system.

9. THE WRITING OF THE ELECTROMAGNETIC RELATIONS

On account of the many different unit systems in use, the electromagnetic relations appear in different forms. The situation is still further complicated by the fact that the practical and so-called absolute or cgs units are mixed, and, instead of systematic physical equations, so-called hybrid or non-systematic equations are obtained. In the various branches of engineering and physics various customary writing styles are observed which are listed in Table V. Since only complete dimension systems are considered, the factor V is a pure numeric, the value of which is identical with the value of the velocity of light in free space, expressed in centimeters per second.

Four of the systems in Table V write the electromagnetic equations in non-systematic form as indicated by the factors 4π or V in the direct relations between physical quantities. No unitary relations between the units can exist. Only two systems are truly "rationalized"; unitary relations hold between the units, and with systematic units no numerical factors appear in the fundamental equations.

Mixed Equations. If in one equation units from different unit systems are employed, this must be stated expressedly in order to avoid serious mistakes. A prominent example is the law of induction, often found in the form $V = -\frac{d\phi}{dt}\cdot 10^{-8}$; in this form V is expressed in volts (practical system) and ϕ in maxwells (cgs electromagnetic system). A proper way of writing this equation with mixed units is $V = -\frac{d\phi}{dt}\cdot 10^{-8}$ (V in volts, ϕ in maxwells).

In general, it is preferable to avoid the use of mixed equations, as it is necessary to remember with the symbols also the numerical factors.

UNITS AND STANDARDS

Dimensions of Units, see Dimension Systems, page 3–02.
Fundamental and Derived Units, see Unit Systems, page 3–12.
Conversion of Units, see Tables 27 to 60, Section 1.

10. LENGTH, MASS, AND TIME

The English Units and Standards

Units of Length. The foot (ft) is the *fundamental* unit of length in the foot-pound-second (fps) system. It equals, by definition, one-third of a *yard* (yd), which is the English legalized *standard* unit of length. The *United States yard* was defined by Act of Congress, July 28, 1866, as 3600/3937 the length of the *meter.* (See Metric System for definitions of metric length.)

In Great Britain, the *Imperial yard* is measured by a bronze bar preserved in the Standards Office, Westminster. Its length, in terms of the *international prototype meter,* is 3600/3937.0113 meter. For engineering purposes, the United States and British *yards* may be considered identical.

As subunits, the *inch* (in.) is defined as $^1/_{12}$ of one standard foot, and the *mil* as the one-thousandth part of one inch. The *nautical mile* (mi) is defined as one minute of arc on the earth's surface at the equator, whereas the United States mile (U. S. mi. statute) is exactly 5280 ft and practically identical with the British mile.

Unit of Capacity (Dry). The bushel (bu) is the *standard* unit of *dry* capacity. The *Winchester bushel* (U. S. standard) has a volume of 2150.42 cu in.

In Great Britain, the *Imperial bushel* (bu) is defined as the volume of 80 lb of pure water at 62 deg fahr, weighed against brass weights in air at the same temperature as the water and with the barometer at 30 in. Its volume is approximately 2219.36 cu in.

Unit of Capacity (Liquid). The *gallon* (gal) is the *standard* unit of *liquid* capacity. The *United States gallon* has a volume of 231 cu in.

---

* G. A. Campbell, *Bull. National Research Council,* No. 93, 1933.

In Great Britain, the *Imperial gallon* is defined as the volume of 10 lb of pure water at 62 deg fahr, weighed against brass weights in air at the same temperature as the water and with the barometer at 30 in. Its volume is approximately 277.420 cu in. The imperial gallon (liquid measure) equals exactly one-eighth of the Imperial bushel (dry measure). As subunits, there are used the quart (qt), which is $^1/_4$ of the standard gallon, and the pint (pt), which is $^1/_2$ qt.

Units of Mass. The pound (avoirdupois) (lb avdp) is the *fundamental* unit of mass in the fps system.* It is also the English legalized *standard* unit of mass. The *United States pound* (*avoirdupois*) was defined by Act of Congress, 1866, as 1/2.2046 kg, but since 1895 there has been used, for greater accuracy, a value which agrees with that given by law as far as the latter is given; namely, 453.5924277 grams. This value is now used by the Bureau of Standards as an exact definition and is the basis of the customary United States weights (Circular 47, Bureau of Standards).

In Great Britain, the *Imperial pound* (*avoirdupois*) is the mass of a *platinum cylinder* preserved in the Standards Office, Westminster. Its legal equivalent is 453.59243 grams. For engineering purposes, the United States and British pounds (avoirdupois) may be considered as identical.

Subunits of mass are the grain (gr), defined as $^1/_{7000}$ of the standard pound (avoirdupois) and the ounce (avoirdupois) (oz-avdp) which is $^1/_{16}$ of the standard pound (avoirdupois). The grain was used as fundamental unit in the so-called foot-gram-second (fgs) system of units prior to 1873.

Weight vs. Mass. Unfortunately, the word " weight " is used in two different senses viz.: (1) by the layman (as well as loosely by the scientist) to designate a given *mass* or quantity of matter; and (2) by the scientist to designate the *pull* in standard gravitational force units which is exerted by the earth upon a piece of matter. The result of the commercial act of "weighing" a specific quantity is independent of the local gravitational pull of the earth, since both spring scales and balances are calibrated locally by comparison with standard masses.

For a method of determining whether or not a balance has equal arms and also for methods of correction of data obtained on an incorrect balance, see discussion on these subjects under the heading Accurate Weighing Procedure in this section.

Auxiliary Fundamental Units and Their Principal Derived Units are defined and discussed under the sections of this handbook pertaining to the topics to which they apply. In general, however, conversion factors are included in the tables of Section I.

For an interesting and rather complete history see British Weights and Measures, London, 1910, by Sir C. M. Watson.

The Metric (or French) Units and Standards

Units of Length. The centimeter (cm) is the *fundamental* unit of length in the cgs system. It equals, by definition, $^1/_{100}$ of a *meter* (m) which is the *standard* unit of length. The *basic* meter for international comparisons is the *international prototype meter* which is the distance, at zero degrees centigrade, between two lines on a platinum-iridium bar located at the International Bureau of Weights and Measures, at Sèvres, France. This meter is the nearest to a duplicate, ever constructed, of the *original* meter which was constructed and deposited in the Archives of the French Republic in 1799. The meter is very nearly equal to one ten-millionth of the distance, measured at sea level, from the equator to either pole.

An interesting history of the development of the *international prototype meter* (as well as the *international prototype kilogram*—see Unit of Mass, below) is given by Wm. Parry, National Bureau of Standards, in Merriman's Civil Engineers' Handbook as follows:

"The use of the meter as the basis of geodetic surveys had become so general throughout Europe that a conference was called in Paris, France, in 1870, for the purpose of establishing a central bureau where the standards of the different countries could be compared. As a result of this conference an International Bureau of Weights and Measures was established near Paris in 1875, by the concurrent action of the principal nations of the world. One of the first tasks undertaken by the Bureau was the construction of exact copies of the meter and kilogram deposited in the Archives. Thirty-one standard meters of iridio-platinum and forty kilograms of the same alloy were constructed and carefully compared with the standards of the Archives and with one another. This great work was completed in 1889, and the meter and kilogram which agreed most nearly with the original standards were called international prototypes, and were deposited at the International Bureau, where they are maintained today subject to the authority of the International Committee on Weights and Measures. The remaining meters and kilograms were distributed by lot to the different nations which contributed to the support of the Bureau. The United States secured two copies of the meter and two copies of the kilogram, which are in the custody of the Bureau of Standards at Washington. One of the meters, known as No. 27, and one kilogram, No. 20, were selected as the United States standards, while the other meter and kilogram are used as secondary standards. It was the declared intention of the International Committee that the various national prototypes should be returned to the International Bureau at regular intervals for the purpose of recomparing them with the international standards and with one another. In this way all measurements based upon metric standards throughout the world are ultimately referred to the international meter and kilogram."

---

* The slug of mass, which is extensively used by engineers and physicists, is (in the English system) the mass to which an acceleration of one foot per second per second would be given by the application of a one-pound force. Unlike the pound of mass, it is not an absolute unit. Under standard gravity conditions, one slug of mass = 32.1739 lb of mass.

Unit of Capacity. The liter (l) is the *standard* unit of capacity. It is defined as the volume of one kilogram of pure water at the temperature of maximum density (4 deg cent) under a pressure of 76 cm of mercury. For all practical purposes, the liter may be regarded as the equivalent of the cubic decimeter, although the former is actually slightly greater, in the amount of less than three parts in one hundred thousand.

Unit of Mass. The gram (g) is the *fundamental* unit of mass in the cgs system.* It equals, by definition, $^1/_{1000}$ of a *kilogram* (kg), which is the *standard* unit of mass. The *basic* kilogram for international comparisons is the *international prototype kilogram* which is a cylinder of platinum-iridium located at the International Bureau of Weights and Measures, at Sèvres, France. This mass is the nearest to a duplicate, ever constructed, of the *original* kilogram which was constructed and deposited in the Archives of the French Republic in 1799. The latter was made as nearly as possible equal to the mass of a cube of pure water at 4 deg cent, the sides of the cube being one-tenth the length of the original meter.

An interesting history of the development of the *international prototype kilogram* is given above under the discussion headed Units of Length.

Weight vs. Mass. See discussion under this same subheading of The English Units and Standards.

Auxiliary Fundamental Units and Their Principal Derived Units are defined and discussed under the sections of this handbook pertaining to the topics to which they apply. In general, however, conversion factors are included in the tables of Section I.

The Standard of Time

Unit of Time. The second (sec) is the *fundamental* unit of time. It equals, by definition, the 1/86,400 part of a mean solar day. The solar day is the interval of time between two successive transits of the sun across a meridian of the earth at the point of observation; this interval varies in length at different times during the year, but the average length of the interval for one year is constant.

Measures of Time. A *solar day* is measured by the rotation of the earth about its axis, with respect to the sun. In *astronomical computations* and in *nautical time* the day commences at noon, and in the former it is counted throughout the 24 hours. In *civil computations* the day commences at midnight, and is divided into two parts of 12 hours each.

A *solar year* is the time in which the earth makes one revolution around the sun. Its average time, called the *mean solar year*, is 365 days, 5 hours, 48 minutes, and 48 seconds, or nearly 365 $^1/_4$ days.

History of the Calendar. The Julian Calendar was established by Julius Caesar, 44 B.C., and by it one day was inserted in every fourth year. This was the same thing as assuming that the length of the solar year was 365 days and 6 hours, instead of the value given above, thus introducing a cumulative error of 11 minutes and 12 seconds every year. This calendar was adopted by the church in 325 A.D., at the Council of Nice. In the year 1582 the annual error of 11 minutes and 12 seconds had amounted to 10 days, which, by order of Pope Gregory XIII, was suppressed in the calendar, and the fifth of October reckoned as the fifteenth. To prevent the repetition of this error, it was decided to leave out three of the inserted days every 400 years, and to make this omission in the years which are not exactly divisible by 400. Thus, of the years 1700, 1800, 1900, and 2000, all of which are leap-years according to the Julian Calendar, only the last is a leap-year according to the Reformed or Gregorian Calendar. This Reformed Calendar was not adopted by England until 1752, when 11 days were omitted from the calendar. The two calendars are now often called the *Old Style* and the *New Style*.

---

* The slug of mass, which is extensively used by engineers and physicists, is (in the metric system) the mass to which an acceleration of one meter per second per second would be given by the application of a one-kilogram force. Unlike the kilogram of mass, it is not an absolute unit. Under standard gravity conditions, one slug of mass = 9.80665 kg of mass.

Accurate Weighing Procedure

To Determine Whether a Balance Has Equal Arms. After weighing an article and obtaining equilibrium, interchange the article and the weights. If equilibrium still obtains, the balance is true (assuming friction negligible); if equilibrium does not obtain, the pan which descends is suspended from the longer arm.

To Weigh Correctly on an Incorrect Balance. " Weigh " the article first on one pan and then on the other. The correct weight is the square root of the product of the apparent weights thus obtained.

11. FORCE, ENERGY, AND POWER

Dynamical and Gravitational Units. According to the use of two different dimension and unit systems, the dynamical (or physical, or "absolute") system and the gravitational (or technical) system, two different sets of units of force, energy, power, and derived quantities are defined in both the English and the metric systems. *One dynamical unit of force* produces an acceleration of unity on unit standard mass. The *gravitational unit of force* is defined as that force required to give a unit standard mass an acceleration equal to that produced by the gravitational pull of the earth. As the acceleration due to gravity, g, varies with location and altitude,* the gravitational unit of force is not constant, and, therefore, its relation to the dynamical unit of force will vary. By international agreement, the value $g_0 = 980.665$ cm per sec per sec $= 32.1739$ ft per sec per sec (British) has been chosen as the standard acceleration of gravity.

Force vs. Weight. The gravitational, or technical, system of units is extensively used in engineering, where it is the practice to measure forces by scales and balances calibrated by comparing them with the pull of the earth upon standard masses. These weighing devices, giving commercial weights, also measure force in gravitational units. Since the gravitational unit of force varies with g, measurements should be compared with the gravitational unit under standard conditions, $g = g_0$. Thus the local value of a force in number of standard gravitational units is g/g_0 times the force measured by scales calibrated locally, or $f = wg/g_0 = mg$. Owing to the manner in which weighing devices are calibrated, $m = w/g_0$ where f is in standard gravitational units.†

For engineering work the variation of g with latitude and elevation is usually negligible, so that the weight might be taken as the approximate value of the local pull of the earth. In scientific computations this slight difference has to be taken into consideration. For corrections required in accurate weighing see International Critical Tables, Vol. 1, p. 73.

These same corrections apply to all quantities, such as energy, pressure, power, and torque, involving the gravitational definition of force.

The English Units

Units of Force. The dynamical or physical unit of force is the *poundal*, defined as the force required to give a mass of one pound an acceleration of one foot per second per second.

The *pound-force* (or weight of the pound mass) is the gravitational or technical unit of force. It is, by definition, the force required to give a mass of one pound an acceleration equal to the value of standard acceleration due to gravity (see Force vs. Weight). If a force is measured by "weighing," the result in pounds weight must be multiplied by g/g_0, the ratio of local to standard acceleration of gravity, in order to obtain the absolute value in pound-force units. For engineering purposes this correction can usually be neglected.

The Unit of Pressure is defined as the unit of force acting upon a unit area. The most commonly employed unit is the *pound* (weight) *per square inch*. With respect to correction for local gravity, see Force vs. Weight, above.

Pressure is measured also by the height in inches of the column of water at 4 deg cent (39.1 deg fahr) or of the column of mercury at 32 deg fahr which it supports. (See Conversion Tables.)

Units of Work or Energy. The foot-poundal is the physical unit of work or energy and is defined as the work done by a force of one poundal in moving a body through the distance of one foot in the direction of the force.

The *foot-pound* (*force*) is the technical unit of work or energy and is defined as the work required to raise a mass (or weight) of one pound through a vertical distance of one foot at standard acceleration of gravity g_0. If measurements are made in places where the local value of the acceleration of gravity g is different from g_0, a correction factor g/g_0 must be applied, if the exact value of work or energy is desired. (See Force vs. Weight.)

---

* The variation of g with latitude ϕ and altitude H is given approximately by (ϕ in degrees, H in meters): $g = 978.039\,(1 + 0.005295 \sin^2 \phi) - 0.000307\,H$. See International Critical Tables, Vol. 1, p. 395.

† Wm. L. De Baufre, Mass, weight, and force, *Proc. Soc. Promotion Engg. Educ.*, 1928, p. 655.

The *British thermal unit* (Btu) is the quantity of heat required to raise the temperature of a one-pound mass of water either at 39 deg fahr (at its maximum density) or at 60 deg fahr, and standard pressure, through 1 deg fahr. The mean British thermal unit is defined as the $^1/_{180}$ part of the heat required to raise the temperature of one pound mass of water from 32 to 212 deg fahr at standard pressure. It is obvious that the reference temperature must be indicated with the unit used.

Units of Power. Power is the time rate at which work is done. Its physical unit is the *foot-poundal per second*, its technical units are the *foot-pound (force) per second*, or the *British thermal unit per second*. The *horsepower* (hp or Hp) is defined as 33,000 ft-lb (force) per min or 550 ft-lb (force) per sec.

Units of Torque. Torque is the effectiveness of a force to produce rotation. It is defined as the product of the force and the perpendicular distance from its line of action to the instantaneous center of rotation. Its physical unit is the poundal-foot, and its technical unit the pound (force)-foot. (Note the reversal of force and length units in the designation of the units of torque as compared with the units of energy or work.)

The Metric Units

Units of Force. The dynamical, or physical, unit of force is the *dyne*, defined as the force required to give a mass of one gram an acceleration of one centimeter per second per second.

The *kilogram force* (or weight of the kilogram mass) is the gravitational or technical unit of force. It is, by definition, the force required to give a mass of one kilogram an acceleration equal to the value of standard acceleration due to gravity. (See Force vs. Weight.) If a force is measured by "weighing," the result in kilograms weight must be multiplied by g/g_0, the ratio of local to standard acceleration of gravity, in order to obtain the absolute value in kilogram-force units. For engineering purposes this correction can usually be neglected.

In the electrotechnical system of units the systematic unit of force is defined as the *joule per meter*, based upon the fundamental definition of the joule. (See Metric Units of Energy.)

The Unit of Pressure is defined as the unit of force acting upon a unit of area. The physical unit is the *barye* or the pressure of one dyne upon one square centimeter. A larger unit is the *bar* or 10^6 baryes, which has been adopted internationally. (The use of bar for one dyne per square centimeter is discouraged.)

The *kilogram force per square meter* is the technical unit of pressure. With respect to correction for local gravity, see Force vs. Weight, above.

Pressure is measured also by the height in centimeters of the column of water at 4 deg cent, or of the column of mercury at 0 deg cent, which it supports. (See Conversion Tables.)

The *normal atmosphere* (*at*), or the standard atmospheric pressure, is defined as the pressure exerted by a column of 76 cm of mercury at sea level and 0 deg cent at standard acceleration of gravity g_0. It is equal to 1.01321 bars or 1.0332 kg force per sq cm and is used extensively in the engineering literature. Some confusion exists since the unit of 1 kg force per sq cm is occasionally called 1 practical atmosphere.

Units of Work or Energy. The *erg* is the physical or so-called absolute unit of work or energy. It is defined as the work done by a force of one dyne acting through the distance of one centimeter. A larger unit is the *theoretical* (or absolute) *joule* defined as 10^7 ergs; it is a systematic unit in the practical electrical unit systems which is based upon the theoretical unit systems. (See Electrical Units.)

The *international joule* is defined as the energy expended during one second by an electric current of one international ampere flowing through a resistance of one international ohm. (See Electrical Units.) The latest value of the international joule is equal to 1.00032 theoretical joules.

The *kilowatt-hour* is the practical unit of energy in electrical metering. It is defined as a theoretical or an international unit (see definition of joule above) and is equal to 3600 × 10^3 joules.

The *meter-kilogram force* (commonly referred to as the kilogram-meter) is the technical unit of work or energy. It is defined as the work required to raise the mass (or weight) of one kilogram through a vertical distance of one meter at standard acceleration of gravity g_0. If measurements are made in places where the local value of the acceleration of gravity g is different from g_0, a correction factor g/g_0 has to be applied, if the exact value of work or energy is desired. (See Force vs. Weight.)

The *gram-calorie* or small calorie is the physical unit of heat energy. It is defined as the quantity of heat required to raise the temperature of one gram mass of water either from 14.5 to 15.5 deg cent or from 19.5 to 20.5 deg cent, at standard pressure. The two values are designated as 15 deg cent cal and 20 deg cent cal, respectively. The mean gram-calorie is defined as $^1/_{100}$ part of the quantity of heat required to raise the temperature of one gram mass of water from 0 to 100 deg cent at standard pressure. The same definitions apply to kilogram-calorie, or large calorie, if the kilogram mass is used as reference standard mass.

The *Ostwald calorie* is the quantity of heat required to raise the temperature of one gram mass from 0 to 100 deg cent. This unit is frequently used by electrochemists and is equal to 100 mean gram-calories.

The *international kilo-calorie* or international steam-table calorie (I T cal) is defined as the 1/860th part of the international kilowatthour. This new unit avoids any reference to the thermal properties of water and was recommended for international adoption at the first International Steam Table Conference (1929).* Its value is very nearly equal to the mean kilo-calorie, 1 I T cal = 1.00037 kilogram-calories (mean).

Units of Power. Power is the time rate at which work is done. Its physical unit is the *erg per second.*

A larger unit is the *theoretical* (or absolute) *watt,* defined as 10^7 ergs per second; it is a systematic unit in the practical electrical unit system which is based upon the theoretical unit systems (see electrical units).

The *international watt* is defined as the power expended by an electric current of one international ampere flowing through a resistance of one international ohm. (See Electrical Units.) The latest value of the international watt is equal to 1.00032 theoretical watts.

The *electrical horsepower* is defined as 746 absolute watts and is commonly used in the United States and in England in rating electrical machinery.

The *meter-kilogram force per second* (commonly referred to as the kilogram-meter per second) is the technical unit of power. The *metric horsepower* is defined as 75 kg-meters per sec and is the most common mechanical unit of power.

Units of Torque. Torque is the effectiveness of a force to produce rotation. It is defined as the product of the force and the perpendicular distance from its line of action to the instantaneous center of rotation. Its physical unit is the dyne-centimeter, and its technical unit the kilogram force meter. (Note the reversal of force and length units in the designation of the units of torque as compared with the units of energy and work.)

12. THERMAL UNITS AND STANDARDS

Temperature

Definition of Temperature. The *temperature* of a body may be defined as its thermal state considered from the standpoint of its ability to communicate heat to other bodies. When two bodies are placed in thermal communication, the one which loses heat to the other is said to be at the higher temperature.

Standard Temperatures. Certain thermal states or " temperatures " may be reproduced and recognized by the fact that definite physical phenomena occur at these temperatures. Such thermal states are called "fixed points," and they may, quite apart from any temperature scale, be specified by the physical phenomena characteristic of those temperatures. The two fundamental fixed points are the ice point and the steam point.

The *ice point* is defined as the temperature of melting ice, which is realized experimentally as the temperature at which pure finely divided ice is in equilibrium with pure, air-saturated water, under standard atmospheric pressure. The effect of increased pressure is to lower the freezing point to the extent of 0.007 deg cent per atmosphere.

The *steam point* is defined as the temperature of condensing water vapor at standard atmospheric pressure, and it is realized experimentally by the use of a hypsometer so constructed as to avoid superheat of the vapor around the thermometer, or contamination with air or other impurities. If the desired conditions have been attained, the observed temperature should be independent of the rate of heat supply to the boiler, except as this may affect the pressure within the hpysometer, and of the length of time the hypsometer has been in operation.

Definition of Temperature Scale. The purpose of establishing a temperature scale is to assign a number to every thermal state or temperature, and to provide a means for determining the temperature of any particular body.

---

* *Mechanical Engineering,* Feb., 1930, pp. 122, 139; Nov., 1935, p. 710.

A *temperature scale* may be defined by (1) selecting definite numbers for certain fixed points, (2) selecting some physical property of a definite substance which varies with temperature, and (3) selecting a mathematical law expressing temperatures on the scale in question in terms of the selected property of the thermometric substance. For example, on the centigrade mercury-in-glass scale, the ice and steam points are numbered 0 and 100 respectively, the relative or "apparent" expansion of a volume of mercury enclosed in glass of a definite kind is the property used, and the mathematical relation used to express temperature on this scale is that equal increments of apparent volume of the mercury in this glass correspond to equal increments of temperature. If some other substance is substituted for mercury, or if glass of a different kind is used, another scale is obtained which agrees with it at 0 and 100 but not at other temperatures.

Although, in general, a temperature scale depends on the thermometric substance as well as on the expression for the temperature in terms of some property of this substance, Lord Kelvin has shown that, if the property selected is the availability of energy, the scale so defined is wholly independent of the substance and depends only on the mathematical relation chosen. Any scale so defined is known as a thermodynamic scale.

The Kelvin Temperature Scale. The temperature scale finally chosen by Lord Kelvin is the one on which the temperature interval from the ice point to the steam point is 100 deg and the ratio of the values of any two temperatures is equal to the ratio of the heat taken in to the heat rejected by a reversible thermodynamic engine working with a source and refrigerator at the higher and lower temperatures respectively. On this scale, which is also known as the absolute thermodynamic scale, the lowest attainable temperature is 0 and the ice point is found experimentally to be 273.16 deg. The steam point therefore is 373.16 deg or 100 deg higher.

The *degree Kelvin* (deg K) or degree of absolute temperature is the absolute unit of temperature and is, for practical purposes, identical with the degree centigrade (deg cent) of the international temperature scale.

The Thermodynamic Centigrade Scale is derived by subtracting from the Kelvin scale a constant number of the proper magnitude to make the ice point 0 deg. On this scale, therefore, the ice and steam points are 0 and 100 deg, respectively, and the so-called absolute zero is − 273.16 deg.

The International Centigrade Scale is a practical representation of the thermodynamic centigrade scale to such a degree of accuracy as is possible with present-day apparatus and methods. It was adopted at the General Conference on Weights and Measures at Sèvres, France, in 1927 and is subject to revision and amendment as improved and more accurate methods of measurement are evolved.

The unit of temperature on the international scale is the *degree centigrade* (deg cent, or deg cent int) and is very nearly equal to $^1/_{100}$ the difference between the temperature of melting ice and the temperature of condensing water vapor under standard atmospheric pressure. (See Metric Units for Pressure.)

The standard of the international temperature scale between − 190 and + 660 deg cent is deduced from the electrical resistance of a standard platinum resistance thermometer by means of a formula connecting the resistance R_t at any temperature t deg cent within the above range with the resistance R_0 at 0 deg cent. The purity of the platinum of which the thermometer is made should be such that the ratio R_t/R_0 for certain fixed temperatures is within specified limits.*

The degree centigrade is most widely used in scientific publications and increasingly also in the engineering literature. In many countries in Europe it is the common everyday temperature unit. The subdivision into a hundred degrees of the temperature interval between the ice point and the steam point was first used by Celsius, a German, in 1742; therefore, in the European literature "° C" is read "degree Celsius."

The Fahrenheit Temperature Scale subdivides the temperature interval between the ice point and the steam point into 180 parts, one part of which is chosen as the unit of temperature and named *degree Fahrenheit* (deg fahr). The ice point is assigned the value 32 deg fahr, so that the steam point has a temperature of 212 deg fahr.

The Fahrenheit unit of temperature is in common everyday use in the English-speaking countries. It was first introduced in England about 1665 by the physicist Fahrenheit; the choice of 32 deg fahr for the ice point has its explanation in the fact that Fahrenheit chose as zero the lowest temperature attainable by means of a salt-ice mixture.

The Réaumur Temperature Scale subdivides the temperature interval between the ice point and the steam point into 80 parts, one part of which is chosen as the unit of temperature and named *degree Réaumur* (deg R). The ice point is assigned the value 0 deg R, as in the centigrade scale, so the steam point has a temperature of 80 deg R.

---

* See also U. S. Bureau of Standards, *Journal of Research*, Vol. 1, p. 636.

The Réaumur unit of temperature is in common everyday use in a number of European countries, especially in France and Russia. It was first introduced by Réaumur, a Frenchman, in 1731.

Relations between the Temperature Scales. In Table VI are shown the interrelations between the various temperature scales in form of equations. *X* indicates the unknown number of chosen temperature units and *t* the known number of given temperature units.

Table VI. Relations between the Temperature Scales

$X°\,F$ =	....	$9/5\,(t°\,K - 273.16) + 32$	$9/5\,(t°\,C) + 32$	$9/4\,(t°\,R) + 32$
$X°\,K$ =	$5/9\,(t°\,F - 32) + 273.16$	....	$(t°\,C) + 273.16$	$5/4\,(t°\,R) + 273.16$
$X°\,C$ =	$5/9\,(t°\,F - 32)$	$(t°\,K) - 273.16$	....	$5/4\,(t°\,R)$
$X°\,R$ =	$4/9\,(t°\,F - 32)$	$4/5\,(t°\,K - 273.16)$	$4/5\,(t°\,C)$	....

Quantity of Heat and Some Derived Quantities

Units of Quantity of Heat. Quantity of heat is defined as the energy transferred from one body to another by a thermal process, i.e., by radiation or conduction. The units for the quantity of heat are the *British thermal unit* and the *caloric*, as specific thermal units; and the *erg* and *joule*, as general physical units (see units of energy, metric and English systems of units).

Thermal Capacity or Specific Heat of a Substance is the quantity of heat required to produce a unit change in temperature in a unit of mass of the substance. The common English unit is the British thermal unit per degree Fahrenheit per pound mass (Btu per deg fahr per lb); the usual metric unit is the gram-calorie per degree centigrade per gram mass (cal per deg cent per g); and the general physical unit used in the scientific literature is the erg per degree centigrade per gram mass (erg per deg cent per g). In the technical literature thermal capacity of a substance is often expressed in watt-seconds (or joules) per degree centigrade per kilogram mass (watt-sec per deg cent per kg) on account of the easy comparison with other technical units.

The Calorimetric or Water Equivalent is the quantity of heat required to produce a unit change in temperature of a body or system. It is numerically equivalent to the mass of water (in units as involved in the definition of the unit of quantity of heat used) which could be raised a unit temperature by the same total quantity of heat. The thermal capacity is expressed in British thermal units per degree Fahrenheit (Btu per deg fahr), calories per degree centigrade (cal per deg cent), or watt-seconds per degree centigrade (watt-sec per deg cent).

Thermal Conductivity is the time rate of heat transfer through unit area across unit thickness per unit difference in temperature between the end surfaces. It is measured in British thermal units per second per degree Fahrenheit per inch thickness per square inch cross-section (Btu per sec per deg fahr per in. per sq in.), in calories per second per degree centigrade per centimeter thickness per square centimeter cross-section (cal per sec per deg cent per sq cm per cm), or in watts per degree centigrade per meter thickness per square meter cross-section (watts per deg cent per sq m per m).

Emissivity or emissive power is the time rate of heat emitted by unit area for unit difference in temperature between the surface in question and the surroundings. It is measured in British thermal units per second per degree Fahrenheit per square inch (Btu per sec per deg fahr per sq in.), in calories per second per degree centigrade per square centimeter (cal per sec per deg cent per sq cm, or in watts per degree centigrade per square meter (watts per deg cent per sq m).

The Joule Equivalent

The Joule Equivalent is defined as the number of foot-pounds of energy per Btu. In Table VII are given the numerical values for the various energy units used in the English and metric systems.*

Table VII.—Relations between Energy Units †

	Joules (theoretical)	Foot-pounds (force)	Foot-poundals	Meter-kilogram (force)	Kilowatt-hour (international)
1 British thermal unit (Btu) (mean) . . =	1055.18	778.26	25,040	107.599	2.93019×10^{-4}
1 gram-calorie (cal) (mean). . . . . =	4.1873	3.0884	99.366	0.42699	1.16279×10^{-6}
1 International kilo-calorie (I T-cal) =	4187.3	3088.4	99,366	426.99	1.16279×10^{-3}
1 Ostwald calorie. . . =	418.73	308.84	9936.6	42.699	1.16279×10^{-4}

* For a rather complete historical account see R. Glazebrook, Dictionary of Applied Physics, Vol. I, p. 477.

† According to the latest computations, see *Mechanical Engineering*, Vol. 57, p. 713 (1935).

13. THE THEORETICAL OR "ABSOLUTE" ELECTRICAL UNITS

The Definitions of the Theoretical Units are based upon the fundamental units of the physical (dynamical) unit system of mechanics, which is very frequently referred to as the " absolute " unit system, and has led to the electrical units being called " absolute " units. This designation is not warranted, as " absolute " implies the meaning of " ultimate." (See discussion on " absolute " electrical unit systems, p. 3-13.) According to a previous proposal,* " absolute " shall be replaced here by " theoretical," a designation which calls the attention to the fact that mere arbitrary definitions, not standards, are the basis of the units. The realization of the " absolute " units has been attempted many times in the past by so-called " absolute " measurements. An interesting account of the history and a description of the various classical methods can be found in Glazebrook's Handbook for Applied Physics, Vol. II, " Electricity," pp. 211 and on, 1922.

The Theoretical Electrostatic Units

The Theoretical Electrostatic Units are based upon the cgs system of mechanical units and are therefore frequently referred to as the *cgs electrostatic units.* No specific unit names are available. In order to avoid the cumbersome writing, for example, one "theoretical electrostatic unit of charge," it had been proposed to use the theoretical "practical" unit names and prefix them with either stat † or E.S.,‡ as for example, statcoulomb, or E.S. coulomb. The first alternative will be used here.

The Absolute Dielectric Constant (Permittivity) of free space is the fundamental quantity in the theoretical electrostatic system of units. Its numerical value is assumed as unity, and it is identical with one centimeter per statfarad if use is made of prefixing the corresponding unit of the "practical" series. As the dielectric constant is a derived quantity in the "practical" unit systems it takes a derived unit name in the electrostatic system although, in fact, it is entitled to a fundamental unit name.

The Theoretical Electrostatic Unit of Charge or the statcoulomb is defined as the quantity of electricity which, when concentrated at a point and placed at one centimeter distance from an equal quantity of electricity similarly concentrated, will experience a mechanical force of one dyne in free space. An alternative definition, based upon the concept of field lines, gives the theoretical electrostatic unit of charge as a positive charge from which in free space exactly 4π electrical field lines emerge. Both these definitions use the numerical value unity for the proportionality constant K_{e0} in Coulomb's law. (See Table V.) The quantity of electricity appears in this system as a derived quantity.

The Theoretical Electrostatic Unit of Displacement Flux (Dielectric Flux) is the " line of displacement flux" or $\frac{1}{4\pi}$ of the theoretical electrostatic unit of charge. This definition provides the basis for graphical field mapping in so far as it gives a definite rule for the selection of displacement lines to represent the character of the field.

The Theoretical Electrostatic Unit of Displacement, or Dielectric Flux Density, is chosen as one displacement line per square centimeter area perpendicular to the direction of the displacement lines. It can be given also as $\frac{1}{4\pi}$ statcoulomb per square centimeter (according to Gauss's law). In isotropic media the displacement has the same direction as the potential gradient, and the surfaces perpendicular to the field lines become the equipotential surfaces; the theoretical electrostatic unit of displacement can then be defined as one displacement line per square centimeter of equipotential surface.

The Theoretical Electrostatic Unit of Electrostatic Potential or the Statvolt is defined as existing at a point in an electrostatic field, if the work done to bring the theoretical electrostatic unit of charge, or the statcoulomb, from infinity to this point equals one erg. This customary definition implies, however, that the potential vanishes at infinite distances and has, therefore, only restricted validity. As it is fundamentally impossible to give absolute values of potential the use of potential difference and its unit (see below) should be preferred.

The Theoretical Electrostatic Unit of Electrical Potential Difference or Voltage, or the Statvolt, is defined as existing between two points in space if the work done to bring the theoretical electrostatic unit of charge, or the statcoulomb, from the one of these points to the other equals one erg. Potential difference is counted positive in the direction in which a negative quantity of electricity would be moved by the electrostatic field.

---

* G. Mie in Handbuch der Experimental Physik, Vol. 11, "Elektrodynamik," p. 430, Berlin, 1932.

† Proposed by A. E. Kennelly at the International Electrical Congress in St. Louis, 1904, *Trans.*, Vol. 1, p. 180, and used by C. Hering, Conversion Tables, J. Wiley and Sons, 1904.

‡ Proposed by A. E. Caswell, *Science*, Vol. 42, p. 695, 1915, and used by E. Bennett. A digest of the relations between the electrical units, *Bull. Univ. Wisconsin*, No. 880, 1917.

The Theoretical Electrostatic Unit of Capacitance of the Statfarad is defined as the capacitance which maintains an electrical potential difference of one statvolt between two conductors charged with equal and opposite electrical quantities of one statcoulomb. In some texts the statfarad is called one "centimeter," which is confusing. (See CGS Electrostatic Unit System.)

The Theoretical Electrostatic Unit of Electric Potential Gradient, or Field Strength (field intensity), is defined to exist at a point in an electric field, if the mechanical force exerted upon the theoretical electrostatic unit of charge concentrated at this point is equal to one dyne. It is expressed as one statvolt per centimeter.

The Theoretical Electrostatic Unit of Current or the Statampere is defined as the time rate of transfer of the theoretical electrostatic unit of charge and is identical with the statcoulomb per second.

The Theoretical Electrostatic Unit of Electrical Resistance or the Statohm is defined as the resistance of a conductor in which a current of one statampere is produced if a potential difference of one statvolt is applied at its ends.

The Theoretical Electrostatic Unit of Electromotive Force (emf) is defined as equivalent to the theoretical electrostatic unit of potential difference if it produces a current of one statampere in a conductor of one statohm resistance. It is identical with the statvolt but, according to its concept, requires an independent definition.

The Theoretical Electrostatic Unit of Magnetizing Force is defined as the magnetizing force at the center of a circle of 4π cm diameter in which a current of one statampere is flowing. This unit is equal to 4π statamperes per centimeter but has no name as the factor 4π excludes the possibility of using the prefixed " practical " unit name.

The Theoretical Electrostatic Unit of Magnetic Flux or the Statweber is defined as the magnetic flux whose time rate of change through a linear conductor loop (linear conductor is used to designate a conductor of infinitely small cross-section) produces in this loop an electromotive force (emf) of one statvolt.

The Theoretical Electrostatic Unit of Magnetic Flux Density, or Induction, is defined as the electrostatic unit of magnetic flux per square centimeter area, or the statweber per square centimeter.

The absolute magnetic permeability of free space is defined as the ratio of magnetic induction to the magnetizing force. Its unit is the stathenry per centimeter, as a derived unit; its value is given in Table V.

The Theoretical Electrostatic Unit of Inductance or the Stathenry is defined as connected with a conductor loop carrying a steady current of one statampere which produces a magnetic flux of one statweber. A more general definition, applicable to varying fields with non-linear relation between magnetic flux and current, gives the stathenry as connected with a conductor loop in which a time rate of change in the current of one statcoulomb produces a time rate of change in the magnetic flux of one statweber per second.

The Theoretical Electromagnetic Units

The Theoretical Electromagnetic Units are based upon the cgs system of mechanical units and are, therefore, frequently referred to as the cgs electromagnetic units. Only a few specific unit names are available. In order to avoid cumbersome writing, for example, one "theoretical electromagnetic unit of charge," it had been proposed to use the theoretical "practical" unit names and prefix them with either ab-[*] or E.M.,[†] as for example abcoulomb, or E.M. coulomb. The first alternative will be used here.

The theoretical electromagnetic units are based essentially upon the assumption of a fictitious magnetic quantity similar to the electric quantity or charge. It must be borne in mind that the phenomenon of magnetism is fundamentally a bipole phenomenon; a separation of positive or negative magnetic quantity has not been possible. Several of the following definitions, therefore, have to be taken cautiously. They are given because of their widespread use in theoretical physics and their continued appearance even in elementary textbooks.

The Absolute Magnetic Permeability of free space is the fundamental quantity in the theoretical electromagnetic system of units. Its numerical value is assumed as unity, and it is identical with one abhenry per centimeter if use is made of prefixing the corresponding unit of the "practical" series. As the permeability is a derived quantity in the practical unit systems it takes a derived unit name in the electromagnetic system, although, in fact, it is entitled to a fundamental unit name.

The Theoretical Electromagnetic Unit of Magnetic Quantity is defined as the magnetic quantity which, when concentrated at a point and placed at one centimeter distance from an equal magnetic quantity similarly concentrated, will experience a mechanical force of one dyne in free space. An alternative definition, based upon the concept of field lines, gives the theoretical electromagnetic unit of magnetic quantity as a positive magnetic quantity from which, in free space, exactly 4π magnetic field lines emerge. Both these definitions use the numerical value, unity, for the proportionality constant in Coulomb's law for magnetic poles. The unit of magnetic quantity thus defined is identical with 4π maxwells.

---

[*] Proposed by A. E. Kennelly at the International Electrical Congress in St. Louis, 1904, *Trans.* Vol. 1, p. 180, and used by C. Hering, Conversion Tables, J. Wiley and Sons, 1904.

[†] Proposed by A. E. Caswell, *Science*, Vol. 42, p. 695, 1915, and used by E. Bennett. A digest of the relations between the electrical units, *Bull. Univ. Wisconsin*, No. 880, 1917.

The Theoretical Electromagnetic Unit of Magnetic Moment is defined as the magnetic moment possessed by a magnet formed by two theoretical electromagnetic units of magnetic quantity of opposite sign, concentrated at two points one centimeter apart. The unit is expressed as 4π maxwell-centimeters.

The Theoretical Electromagnetic Unit of Magnetic Flux is the "field line," or $\frac{1}{4\pi}$ times the theoretical electromagnetic unit of magnetic quantity, and is called one maxwell. This definition provides the basis for graphical field mapping since it gives a definite rule for the selection of field lines to represent the character of the magnetic field.

The Theoretical Electromagnetic Unit of Magnetic Flux Density, or Induction, is chosen as one magnetic field line per square centimeter area perpendicular to the direction of the field lines. It can also be given as one maxwell per square centimeter and is called one gauss.

The Theoretical Electromagnetic Unit of Magnetizing Force (Magnetic Intensity) is defined as the magnetizing force which exerts a mechanical force of one dyne upon the theoretical electromagnetic unit of magnetic quantity concentrated at the point. The name of this unit is oersted.

The Theoretical Electromagnetic Unit of Current, or the Abampere, is defined as the current which flows in a circle of one centimeter diameter and produces at the center of this circle a magnetizing force of one oersted.

The Theoretical Electromagnetic Unit of Inductance, or the Abhenry, is defined as connected with a conductor loop in which a time rate of change of one maxwell per second in the magnetic flux produces a time rate of change in the current of one abcoulomb per second. In some texts the abhenry is called "centimeter," which is confusing. (See CGS Electromagnetic Unit System.)

The Theoretical Electromagnetic Unit of Magnetomotive Force (mmf) is defined as the magnetic driving force produced by a conductor loop carrying a steady current of $\frac{1}{4\pi}$ abamperes; it has the name one gilbert. The concept of magnetomotive force as the driving force in a "magnetic circuit" permits an alternative definition of the gilbert as the magnetomotive force which produces a uniform magnetizing force of one oersted over a length of one centimeter in the magnetic circuit. Obviously, one gilbert equals one oersted-centimeter.

The Theoretical Electromagnetic Unit of Magnetostatic Potential is defined as that existing at a point in a magnetic field, if the work done to bring the theoretical electromagnetic unit of magnetic quantity from infinity to this point equals one erg. (This customary definition implies, however, that the potential vanishes at infinite distances, and the definition has, therefore, only restricted validity.) The unit, thus defined, is identical with one gilbert. The difference in magnetostatic potential between any two points is usually called magnetomotive force (mmf).

The Theoretical Electromagnetic Unit of Reluctance is defined as the reluctance of a magnetic circuit in which a magnetomotive force of one gilbert produces a magnetic flux of one maxwell.

The Theoretical Electromagnetic Unit of Electric Charge, or the Abcoulomb, is defined as the quantity of electricity which passes through any section of an electric circuit in one second if the current is one abampere.

The Theoretical Electromagnetic Unit of Displacement Flux (Dielectric Flux) is the "line of displacement flux" or $\frac{1}{4\pi}$ of the theoretical electromagnetic unit of electric charge. This definition provides the basis for graphical field mapping in so far as it gives a definite rule for the selection of displacement lines to represent the character of the field.

The Theoretical Electromagnetic Unit of Displacement, or Dielectric Flux Density, is chosen as one displacement line per square centimeter area perpendicular to the direction of the displacement lines. It can also be given as $\frac{1}{4\pi}$ abcoulombs per square centimeter (according to Gauss's law). In isotropic media the theoretical electromagnetic unit of displacement can be defined as one displacement line per square centimeter of equipotential surface. (See Theoretical Electrostatic Unit of Displacement.)

The Theoretical Electromagnetic Unit of Electrical Potential Difference or Voltage, or the abvolt, is defined as the potential existing between two points in space if the work done in bringing the theoretical electromagnetic unit of charge, or the abcoulomb, from one of these points to the other equals one erg. Potential difference is counted positive in the direction in which a negative quantity of electricity would be moved by the electrostatic field.

The Theoretical Electromagnetic Unit of Capacitance, or the Abfarad, is defined as the capacitance which maintains an electrical potential difference of one abvolt between two conductors charged with equal and opposite electrical quantities of one abcoulomb.

The Theoretical Electromagnetic Unit of Potential Gradient, or Field Strength (field intensity), is defined to exist at a point in an electric field if the mechanical force exerted upon the theoretical electromagnetic unit of charge concentrated at this point is equal to one dyne. It is expressed as one abvolt per centimeter.

The Theoretical Electromagnetic Unit of Resistance, or the Abohm, is defined as the resistance of a conductor in which a current of one abampere is produced if a potential difference of one abvolt is applied at its ends.

The Theoretical Electromagnetic Unit of Electromotive Force (emf) is defined as the electromotive force acting in an electric circuit in which a current of one abampere is flowing and electrical energy is converted into other kinds of energy at the rate of one erg per second. This unit is identical with the abvolt.

The Absolute Dielectric Constant of Free Space is defined as the ratio of displacement to the electric field intensity. Its unit is the abfarad per centimeter, a derived unit; its value is given in Table V.

The Theoretical Electrodynamic Units

The Theoretical Electrodynamic Units are based upon the cgs system of mechanical units and are therefore frequently referred to as *the cgs electrodynamic units.* In contradistinction to the theoretical electromagnetic units, these units are derived from a significant experimental law, Ampère's experiment on the mechanical force between two parallel currents. (See Table V.) The units as proposed by Ampère and used by W. Weber differ from the electromagnetic units by factors of 2 and multiples thereof. They can be made to coincide with the theoretical electromagnetic units by proper definition of the fundamental unit of current. Some of the important definitions will be given for this latter case only.

For the *absolute magnetic permeability* of free space see Theoretical Electromagnetic Units.

The Theoretical Electrodynamic Unit of Current, or the Abampere, is defined as the current flowing in a circuit consisting of two infinitely long parallel wires one centimeter apart when the electrodynamic force of repulsion between the two wires is *two* dynes per centimeter length in free space. If the more natural choice of *one* dyne per centimeter length is made, the original proposal of Ampère is obtained and the unit of current becomes $^1/_2$ abampere.

The Theoretical Electrodynamic Unit of Magnetic Induction is defined as the magnetic induction inducing an electromotive force of one abvolt in a conductor of one-centimeter length and moving with a velocity of one centimeter per second, if the conductor, its velocity, and the magnetic induction are mutually perpendicular. The unit thus defined is called one gauss.

The Theoretical Electrodynamic Unit of Magnetic Flux, or the Maxwell, is defined as the magnetic flux represented by a uniform magnetic induction of one gauss over an area of one square centimeter perpendicular to the direction of the magnetic induction.

The Theoretical Electrodynamic Unit of Magnetizing Force, or the Oersted, is defined as the magnetizing force at the center of a circle of 4π-centimeter diameter in which a current of one abampere is flowing.

All the Other Unit Definitions, which do not pertain to magnetic quantities, are identical with the definitions for the theoretical electromagnetic units.

The Rational Units

The factor 4π occurs frequently in the definition of important units. According to Heaviside, this can be avoided by writing the fundamental electromagnetic equations in a form different from and simpler than that used by the classical authors. The form of the equations is given in Table V, and the unit definitions, which are based upon the definitions of the theoretical electromagnetic units, lead to the " rationalized " units as shown in Table IV. On account of the convenience many authors use the rationalized forms of the equations but very seldom use the rationalized units. Usually conversion into the " practical " units is preferred for any numerical computations.

The So-called " Absolute " Practical Units

The units of the theoretical electrostatic and electromagnetic series are not particularly convenient for most purposes. The "practical" series of units uses multiples and submultiples of the theoretical electromagnetic units in such manner that no new numerical factors enter the fundamental equations and that the systematic unit of energy is the joule instead of the erg. Since these "practical" units are based upon the theoretical classical units they are, in fact, also theoretical. In order to distinguish these units from the international series (see below), the former are frequently referred to as "absolute" practical units.

The Fundamental Unit Names and their relations to the theoretical units follow, with indication of the year of their international adoption.

The ampere is 10^{-1} of the theoretical electromagnetic unit of current (1881).
The coulomb is 10^{-1} of the theoretical electromagnetic unit of charge (1881).
The volt is 10^{+8} of the theoretical electromagnetic unit of potential difference (1881).
The ohm is 10^{+9} of the theoretical electromagnetic unit of resistance (1881).
The henry is 10^{+9} of the theoretical electromagnetic unit of inductance (1893).
The farad is 10^{-9} of the theoretical electromagnetic unit of capacitance (1881).
The weber is 10^{+8} of the theoretical electromagnetic unit of magnetic flux (1933).
The joule is 10^{+7} ergs (1889).
The watt is 10^{+7} ergs per second (1889).

The definitions of these theoretical "practical" units are similar to the definitions of the theoretical electromagnetic units and are obtained from them if the prefix **ab-** is omitted and erg or dyne is replaced by joule or joule per centimeter, respectively.

In addition, the definitions of dielectric and magnetic quantities, which formerly involved the factor 4π, are to be replaced as follows:

The Theoretical " Practical " Unit of Magnetomotive Force (mmf) is defined as the magnetic driving force produced by a conductor loop carrying a steady current of one ampere; it has the name ampere-turn. The concept of magnetomotive force as the driving force in the "magnetic circuit" permits the alternative definition of the ampere-turn as the magnetomotive force which produces a uniform magnetizing force of one ampere per centimeter over a length of one centimeter in the magnetic circuit.

The Theoretical " Practical " Unit of Magnetizing Force (Magnetic Intensity) is defined as the magnetizing force at the center of a circle of one-centimeter diameter in which a current of one ampere is flowing. It is expressed as one ampere-turn per centimeter.

The Theoretical " Practical " Unit of Reluctance is defined as the reluctance of a magnetic circuit in which a magnetomotive force of one ampere-turn produces a magnetic flux of one weber.

The Theoretical " Practical " Unit of Displacement Flux (Dielectric Flux) is defined as the total displacement flux emanating from a positive theoretical " practical" unit of charge, or coulomb. It is expressed as one coulomb.

The Theoretical " Practical " Unit of Displacement (Dielectric Flux Density) is defined as one coulomb of displacement flux uniformly distributed over the area of one square centimeter perpendicular to the direction of the displacement. It is expressed as one coulomb per square centimeter.

The Unit System, Which Uses the " Practical " Units, as defined in the rationalized equations, employs the absolute dielectric constant and the absolute permeability of free space as physical quantities with numerical values which are given in Table V.

The Derived Theoretical " Practical " Units can be formed either in the cgs system or in the mks system. In general, the centimeter is preferred as it gives the more convenient values for densities, whereas the meter would be preferable from the point of view of the comprehensive Giorgi-MKS system. Both alternatives are given in Table V for the more important electrical quantities.

The Bureau Internationale des Poids et Mesures decided in 1933 to replace the "international" practical units by the "absolute" practical units. At the meeting on October 8, 1935, it decided to set as the final date for this transition the year 1940.

14. THE INTERNATIONAL ELECTRICAL UNITS AND STANDARDS

Definitions of the Internationally Adopted Units [*]

The International System of electrical and magnetic units is a system for electrical and magnetic quantities which takes as the four fundamental quantities resistance, current, length, and time.

The units of resistance and current are arbitrary values that approximately correspond to the theoretical or "absolute" ohm and the theoretical or "absolute" ampere, and the units of length and time are the centimeter and second.

The international units were defined by the International Electrical Congress at Chicago in 1893 and slightly modified by the London Electrical Conference in 1908. (The International Committee of Weights and Measures has decided to discard these units in the near future.)

The International Ampere is defined as the current which will deposit silver at the rate of 0.00111800 gram per second.

Experimental results show that the international ampere is nearly the same as the theoretical ampere.[†]

An International Coulomb is the quantity of electricity which passes any section of an electrical circuit in one second, when the current in the circuit is one international ampere.

One international coulomb is nearly the same as the theoretical coulomb.

The International Ohm is defined as the resistance at 0 deg cent of a column of mercury of uniform cross-section, having a length of 106.300 cm and a mass of 14.4521 grams.

Experimental results show that one international ohm equals 1.0005 theoretical ohms.[‡]

The International Volt is the voltage that will produce a current of one international ampere through a resistance of one international ohm.

One international volt equals 1.0005 theoretical volts.

The International Henry is the inductance which produces an electromotive force of one international volt when the current is changing at the rate of one international ampere per second.

One international henry equals 1.0005 theoretical henrys.

The International Farad is the capacitance of a capacitor if a charge of one international coulomb produces a potential difference between the terminals of one international volt.

One international farad equals 0.9995 theoretical farad.

The International Joule [§] is the energy required to transfer one international coulomb between two points having a potential difference of one international volt.

One international joule equals 1.0005 theoretical joules.

The International Watt [§] is the power expended when one international ampere flows between two points having a potential difference of one international volt.

One international watt equals 1.0005 theoretical watts.

Definitions of Auxiliary Units

In addition to the internationally adopted units, a number of auxiliary units are in use, based upon the former and derived from them.

The International Ampere-turn is the magnetomotive force of a conductor loop in which a current of one international ampere is flowing.

The International Mho is the unit of conductance and is defined as the reciprocal value of one international ohm. It is represented by the same column of mercury which serves as standard for the international ohm.

The Faraday is the electrical charge carried by one gram-equivalent of dissociated substance. It is identical with 96,507 international coulombs.

The International Kilowatt-hour is the practical unit of energy in electrical metering. It is defined as 3600×10^3 international joules.

The International Unit of Magnetic Flux is the international volt-second and is defined as the magnetic flux through a conductor loop with a resistance of one international ohm, when the reversal of direction of the magnetic flux causes the transfer of one international coulomb in the conductor loop. The international volt-second equals 1.0005 theoretical volt-seconds or webers.

---

[*] Proposed American Standard definitions of electrical terms, A.I.E.E. No. 2, August, 1932, p. 33.

[†] The latest determination of the ratio, international ampere to theoretical ampere, gives the value 0.999928 ± 0.000020; H. L. Curtis and R. W. Curtis, *Bur. Standards J. Research*, 1934, Vol. 12, p. 665.

[‡] The latest determination of the ratio, international ohm to theoretical ohm by the N.P.L. (National Physical Lab., England) gives the value 1.00052, F. E. Smith, *Phil. Trans. Roy. Soc. London*, Vol. 214, p. 27, 1914; by the P.T.R. (Physikalisch-Technische Reichsanstalt gives the value 1.00051, E. Grüneisen and E. Giebe, *Ann. Physik*, Vol. 63, p. 179, 1920.

[§] The latest computation, 1935, of the ratio of the international to the theoretical joule and watt gives the value, 1.00032.

Definitions of Derived Units

From the eight internationally adopted and the five auxiliary international units, other units can be derived as densities and gradients. These derivatives can be formed with either the cgs system of mechanical units or the mks system and correspondingly lead to different numerical relations.

Derived Units in the CGS System. In the engineering as well as in the scientific literature the centimeter is much the preferred length unit because it gives convenient values for the derived quantities. To form a comprehensive unitary system, however, the systematic unit of mass should then be one gram-seven (10^7 gram mass), which has been advocated and partially used. (See CGS System of Units, p. 3-14.) The units of the more important electrical derived quantities, using the centimeter as unit length, are shown in Table VII under practical unit system, with the values in the left sub-column.

Derived Units in the MKS System. Although advocated since 1901 and based upon the true standards of mechanical units (see MKS System of Units, p. 3-14), the mks system has not been used in connection with electrical units. It seems to be the only reasonable comprehensive unitary system of units, yet its values for densities and gradients are inconveniently large. The units of the more important electrical derived quantities, using the meter as unit length, are shown in Table IV under practical unit system, with the values in the right sub-column.

Derived Units in the English System. In the engineering literature of the English-speaking countries the foot-pound-second system is usually employed in order to form the derived units. As unit length either the inch or the mil (one-thousandth of the inch) is chosen; as unit area the square inch or the circular mil (for circular cross-sections). In most scientific publications, however, the metric system is used or the equivalent values in the metric system are given.

The Writing of the Electromagnetic Equations is not influenced by the choice of the supplementary mechanical system used for the derived units, if the *same units* are used on *both sides of the equations*, and no new numerical factors will enter. If units from different systems are used, this fact must be expressedly stated, and the equations will need numerical factors in order to balance the two sides.

Historical

Many controversies and discussions have been instigated by the almost continuous change in electrical standards. It is difficult to compare results of more recent precision measurements with earlier ones because the conditions of the standards used then might not be known accurately enough or it might not even be known which definitions of the standards were employed. A very interesting account of the history of the international electrical units is given by A. E. Kennelly in *Proc. Soc. Promotion Engg. Educ.*, Vol. 19, p. 229, 1928.* A short review of the historical development follows here.

First Empirical Standards. The " absolute " measurements of magnetic quantities by C. F. Gauss (1833), and electrical quantities by W. Weber (1840, 1851), showed the possibility of comparing electromagnetic quantities with mechanical quantities. Comparative measurements demonstrated the need for "standards" as they existed in the meter and kilogram prototypes. The earliest attempt was by Charles Wheatstone (1843), who used 1-ft lengths of copper wire, weighing 100 grains (6.48 grams). The Jacobi etalons (1850) and the Siemens unit (1860) followed. The latter is a mercury column of 1 sq mm cross-section and 1 meter length under specified conditions and has a resistance of nearly 1 ohm (1 international ohm = 1.06300 Siemens units).

First Systematic Standards. The confusion in standards brought about the appointment of a "Committee on electrical resistance" by the British Association for the Advancement of Science which worked from 1861 to 1873 and enlisted the collaboration of Lord Kelvin, J. P. Joule, J. C. Maxwell, and others. This committee † recommended the cgs system for general use in science, defined the theoretical "practical" units of volt, ohm, and farad, and issued a standard resistance, the B.A. unit (B.A.U.), which equals 0.988 theoretical ohm, although it was intended to be exactly one theoretical ohm. The lack of more accurate methods of measurement was a severe handicap. In 1872 L. Clark produced a standard cell which gave a fairly constant voltage of 1.43 volts, but no standardization was recommended.

† Reports published by F. Jenkins, London, 1873.

The Congresses at Paris. In 1881 an international electrical congress met at Paris and adopted for international use the theoretical units ohm, volt, ampere, coulomb, and farad. It decided upon resistance as the primary standard, of the same type as the Siemens unit, but left the detail specifications to future investigations. The desired accuracy was specified in 1882 as one per mil (whereas mechanical measurements could be made with considerably higher accuracy). Up to 1884 fourteen independent measurements of the Siemens unit in terms of the theoretical ohm were made in all major countries but the accuracy of one per mil could not be attained, so a " legal " ohm was defined as 1.06 Siemens units. The legal ohm was clearly recognized as a provisional standard until more accurate methods should be available, but it was in wide use for a considerable time.

In 1887 the Physikalisch-Technische Reichsanstalt (P.T.R.) was founded in Berlin, and immediately proceeded to refine the so-called "absolute" measurements under the guidance of H. v. Helmholtz. Up to the international congress in 1889 at Paris, not enough material could be presented, and so a change of the legal ohm was not feasible. The congress adopted, however, the theoretical joule, watt, and kilowatt (instead of the horsepower), and the quadrant (as unit of inductance), for international use.

Introduction of Three International Standards. The fourth international electrical congress at Chicago, 1893, adopted finally the specific definitions of the standards for the "international" ohm and ampere, which had been prepared at a preliminary meeting at Edinburgh (1892). Unfortunately, a third independent standard was adopted, when the Clark cell of standard make was defined as producing a voltage of 1.434 "international" volts at 15 deg cent. Shortly afterwards it was discovered that the international volt as defined from one international ampere × one international ohm differed slightly from the standard defined by the Clark cell. Disagreeable confusion resulted as all measurements had to indicate which standards were used, and troublesome corrections had to be made before measurements using different standards could be compared. Of great help was the formation of the National Physical Laboratories (N.P.L.) in London, 1902, and the Bureau of Standards (B. St.) in Washington, D. C., 1904, followed by other government institutions. At the international meeting at St. Louis, no action could yet be taken, but an international commission was appointed to study a feasible final settlement.

The Final Standards. At a preliminary international conference at Berlin-Charlottenburg, in 1905, definite proposals were prepared, but additional experimental material was requested. The meeting of the international commission in London, 1908, finally adopted the definitions of the "international" units as used today, with the ohm as the first and the ampere as the second primary standard, whereas the volt was defined as a derived unit. The values remained the same as defined at the Chicago congress, but the two zeros were added to make the decision a final one without further corrections. All further measurements could have only the purpose of defining the ratio of the "international" units to the theoretical units, and these efforts have continued. In June, 1929, the International Bureau of Weights and Measures decided to act as a central institute for the intercomparison of the national standards, basing its measurements upon the theoretical units which, according to newest methods, are subject to a very much higher degree of precision than the standards that are kept at the various governmental institutions.*

DIMENSIONAL ANALYSIS

15. DIMENSIONAL HOMOGENEITY OF PHYSICAL EQUATIONS

A Physical Quantity is defined by unit and numerical value. (See Art. 1). The designation by a mathematical symbol is, therefore, not a unique determination, and proper care has to be taken in all cases where physical quantities are used in mathematical equations. The ratio of any two like physical quantities, however, represents a unique and absolute value, provided both quantities are given in the same unit. This is the basis of physical measurements and also of fixed unit relations, as, for example, 1 meter = 100 cm.

Physical Equations are relations between physical quantities which, in general, state the balance of certain conceptual quantities as forces, energies, voltage drops, currents, momenta, and so on. Obviously all the terms in a physical equation must have the same resultant dimension if the equation is to have sense. This property of physical equations is called *dimensional homogeneity* and can be checked by employing the method of dimensions as used first by Fourier.[*] (See Arts. 1 and 2.) In physical differential equations the differentials are to be treated as having the same dimension as the finite quantities. To use dimensional relations properly, one must adhere to a complete dimension system and must not use incomplete dimension sets; this is of particular importance in dimensional analysis as shown later.[†] Proportionality constants, for example, will in general be physical quantities with numerical values and dimensions.

---

* H. L. Curtis, The establishment and maintenance of the electrical units, *Bull. National Research Council*, No. 93, 1933.

A Complete Dimension System suitable for a particular physical equation can be obtained from the equation itself in the following manner. Suppose z quantities are involved in the equation which is composed of q terms of equal resultant dimensions on account of dimensional homogeneity. Between the z dimensions there are, of course, $(q - 1)$ independent relations at the most, so that $(q - 1)$ dimensions can be expressed in general in terms of the remaining $(z - q + 1)$ dimensions. $(z - q + 1)$ constitutes thus the least number of independent or free dimensions in this particular case.

Style. It is of value and utmost convenience to use a definite *style of writing physical equations*. The simplest and most logical expression appears to be the *unitary homogeneous form*, which, of course, involves dimensional homogeneity and is based upon the assumption that one system of units and one only shall be used for all physical quantities involved. Unitary homogeneous equations are independent of the specific unit system employed and can always be reduced to purely numerical relations since all the units cancel on account of the dimensional homogeneity; consequently they avoid the necessity of furnishing a legend with each equation in order to explain the various units to be used. Very illustrative examples of equations not having unitary homogeneity are given by Table VII in Art. 12.

Functional forms (like trigonometric or exponential functions) can have only numerical arguments; sin E, where E means energy, or voltage, has no sense because it violates dimensional homogeneity. This can be seen by expanding the function into the equivalent power series

$$\sin E = \frac{E}{1!} - \frac{E^3}{3!} + \frac{E^5}{5!} - + \cdots$$

where each term has different dimensions.

Physical Similarity

Physical Similarity can be defined as existing for two systems which are described by exactly the same differential equations with exactly the same numerical constants. This at once discards the meaning of similarity as an absolute property and brings it into the same order of approximation as the differential equation describing the phenomena. In general, difficulties do not arise from the assumption of similarity as an absolute property, but rather from the application of this concept to approximately similar systems.

Practical Similarity, as wanted for extrapolation (or model) experiments, is a vague expression and of doubtful value unless the degree of approximation is stated, or the variables enumerated with respect to which similarity is desired. Practical similarity, therefore is not a matter of mathematics; it belongs to the physical concept of a phenomenon, and it is the "classifying process" of the experimenter.[‡] If it is found that two systems can be described approximately by the same differential equation, the same variables and constants, then these two systems are called approximately similar, never exactly similar.

It is possible to formulate similarity conditions for two systems suspected to be physically similar. The same information can be gained from a correctly written differential equation as can be gained from proper dimensional analysis. Never, however, can information be gained about physical constants and universal constants without resorting to tricky semi-mathematics. Physical constants are defined by fundamental relations and are not amenable to any analysis.

16. CLASS PARAMETERS AND SIMILARITY CONDITIONS

A differential equation constituting a relation between an unknown physical quantity y, an independent physical variable x, and certain physical parameters Q_i of the symbolic form

$$D\left(Q_i,\ y,\ \frac{dy}{dx},\ \frac{d^2 y}{dx^2},\ \ldots\right) = 0 \tag{1}$$

---

[*] J. B. J. Fourier, Théorie analytique de la chaleur, p. 391, Paris, 1822.

[†] P. W. Bridgman, Dimensional Analysis, Yale Univ. Press, 1922.

[‡] N. R. Campbell, *Phil. Mag.* (6), Vol. 47, p. 482, 1924.

can be treated as a mathematical differential equation. No definite style of writing the differential equation is required for the mathematical solution. If, however, unitary homogeneity of the differential equation is established, a number of deductions are possible which have profound physical significance.

To have concrete expressions, assume the differential equation to be in the form

$$a_n \frac{d^n y}{dx^n} + a_{n-1} \frac{d^{n-1} y}{dx^{n-1}} + \dots a_1 \frac{dy}{dx} + a_0 y = F \tag{2}$$

where the coefficients a_k may depend on the parameters Q_i, the main variable y or its derivatives, and the independent variable x, in any manner whatsoever, so that nonlinear types of equations are equally well included. If the equation is logically written, unitary homogeneity must prevail. Assuming this, the following deductions can be made:

1. Numerical Parameters. The quotients of any two additive terms in the equation are pure and unique numbers, independent of the special units employed. Since the differential quotients $\frac{d^k y}{dx^k}$ all have dimensions y/x^k, we obtain

$$\frac{a_k\, y/x^k}{a_\nu\, y/x^\nu} = \text{number}, \quad \frac{a_k\, y/x^k}{F} = \text{number} \tag{3}$$

The values of all the numbers will, in general, depend upon the specific characteristic physical constants of the substance studied, the variable x, and the applied disturbance F. Some of these numbers will not contain the variable x explicitly; they are fundamental parameters and could be given proper names (like Reynold's number), if so desired. They can have "critical" values, which in turn will decide the type of solution or the validity of the special assumptions implied in the differential equation.

2. Dimensionless Products. Since the combinations of physical quantities in equation 3 are dimensionless numbers, their mutual products and quotients, and, in fact, any combination of them, will still be dimensionless. They constitute the "numerical" parameters (if they do not contain x explicitly) and the "numerical" variables (if they contain x explicitly) of the problem and must reappear in the mathematical solution. If desired, they might be called "dimensionless products" Π_ν, and the solution written in symbolical form

$$\psi(\Pi_1, \Pi_2, \Pi_3, \Pi_4, \dots \Pi_N) = 0 \tag{4}$$

The number N of independent products is equal to $z - k$, where z is the total number of physical quantities involved (counting also the dimensional physical constants) and k the necessary number of fundamental units for the special physical field ($k = 3$ in mechanics, $k = 4$ in thermodynamics and in electromagnetism, and $k = 5$ for the general combination of all fields). In order for equation 4 to present a complete solution, the $\Pi_1 \dots \Pi_N$ must be truly independent; they must not be mutually deducible by multiplication or division. Of course, it is possible to have ratios of like quantities and other numbers involved in the complete solution, which never can be obtained by discussion.

3. The Class Parameters. Considering any differential equation as characteristic for a "type" of problems, the numerical parameters and variables are then identical with the "typical" or class parameters and variables, which should be chosen for graphical representations of typical solutions. The N independent class variables or parameters can be selected arbitrarily, according to convenience, from among the much larger number of possible combinations. It seems advantageous, if possible, to let only one dimensionless product, for example Π_1, contain the variable y and to write explicitly

$$\Pi_1 = \phi(\Pi_2, \Pi_3, \Pi_4, \dots \Pi_N) \tag{4a}$$

where, of course, ϕ is in general given by the mathematical solution of the differential equation. This form is particularly valuable if a direct solution of the differential equation 2 is impossible. Then, of course, ϕ will not be a known function but equation 4*a* will serve to bring out the class variables for experimental study.

4. The Similarity Conditions. If all the physical parameters and variables be referred to another system and medium according to

$$F = \phi F', \ Q_i = q_i\, Q'_i, \ x = \xi x', \ y = \eta y' \tag{5}$$

then all the coefficients in equation 2 will become

$$a_\kappa = \alpha_\kappa\, a'_\kappa \tag{5a}$$

where α_κ is some combination of the q_i, ξ, and η quantities. Introducing these into the differential equation 2,

$$\left(\alpha_n \frac{\eta}{\xi^n}\right) a'_n \frac{d^n y'}{dx'^n} + \left(\alpha_{n-1} \frac{\eta}{\xi^{n-1}}\right) a'_{n-1} \frac{d^{n-1} y'}{dx'^{n-1}} + \dots \left(\alpha_1 \frac{\eta}{\xi}\right) a_1' \frac{dy'}{dx'} + (\alpha_0\, \eta) a'_0\, y' = \phi F' \tag{6}$$

Obviously the same differential equation will hold, or the two systems will react "similarly," if

$$\left(\frac{\alpha_n}{\xi^n}\cdot\frac{\eta}{\phi}\right)=1,\left(\frac{\alpha_{n-1}}{\xi^{n-1}}\cdot\frac{\eta}{\phi}\right)=1,\ldots\left(\frac{\alpha_1}{\xi}\cdot\frac{\eta}{\phi}\right)=1,\left(\alpha_0\cdot\frac{\eta}{\phi}\right)=1 \tag{7}$$

which are the *complete similarity conditions* for two systems with respect to the phenomenon described by differential equation 2. They cannot, in any case, be the absolute similarity condition as no absolute similarity is possible.

5. Critical Values of the Class Parameters. The general form (4*a*) of the solution in terms of class parameters is subject to the assumptions implied in the differential equation. Only experiments can tell whether or not a differential equation is a satisfactory approximation to the proper description of a phenomenon. In general, any solution will be satisfactory for a certain range of the parameters involved. The limiting values of the class parameters, beyond which the specific approximation becomes poor, are often referred to as *critical* values, because they give a criterion for certain phenomena to occur in a certain manner described by the differential equation. It is, of course, necessary to take into account the simultaneous values of all class parameters characteristic for a phenomenon. This leads, in graphical representation, with the class parameters as coordinates, to *regions* of types of solutions according to the number of variables. All the phenomena that come into these ranges of parameters form a "group" which always can be represented by a single type of solution no matter in which field of physics the phenomena might occur. This fact forms the basis of analogies from other fields, as, for example, electromagnetic phenomena are often likened to flow phenomena of incompressible liquids, if certain conditions of stationarity are satisfied.

Example

Stationary Flow of a Viscous Fluid through a Pipe

To illustrate the above point in the analysis of a differential equation, assume as an example the equation for the stationary flow of a viscous fluid through a pipe

$$\frac{\partial v}{\partial t}=G_z-\frac{1}{\rho}\frac{\partial p}{\partial z}+\frac{\mu}{\rho}\left(\frac{\partial^2}{\partial r^2}+\frac{1}{r}\frac{\partial}{\partial r}\right)v \tag{8}$$

(See A. G. Webster, Differential Equations of Mathematical Physics, Chap. 1.) To equation 8 the equations of continuity and compressibility have to be added in order to furnish the relations between velocity, pressure, and density of the fluid; since the additional relations add nothing from the point of view of dimensions they will not be considered here. The symbols in (8) denote, respectively, with their dimensions in the technical dimension system:

G_z	body force acting per unit mass, or acceleration $[FM^{-1}] = [LT^{-2}]$.
p	hydrodynamic pressure $[FL^{-2}]$.
ρ	density $[ML^{-3}] = [FL^{-4}T^2]$.
v	the axial velocity $[LT^{-1}]$.
μ	viscosity coefficient $[FL^{-2}T]$.
r	radial distance involved in the differentiations $[L]$.
t	time $[T]$.

The differential equation 8 shows dimensional homogeneity as can be checked by the ordinary method of mechanical dimensions and is also unitary homogeneous as it is independent of the units used. It is, therefore, proper to apply the analysis indicated above.

1. The Numerical Parameters. The four terms of equation 8 have the following resultant dimensions which must be identical:

$$\left[\frac{\partial v}{\partial t}\right]=\left[\frac{v}{T}\right],\ [G]=[G],\ \left[\frac{1}{\rho}\frac{\partial p}{\partial z}\right]=\left[\frac{p}{\rho L}\right],\ \left[\frac{\mu}{\rho}\frac{\partial^2 v}{\partial r^2}\right]=\left[\frac{\mu v}{\rho L^2}\right] \tag{9}$$

Forming the mutual quotients by dividing the first term successively by all the following ones, then the second term by the following ones, and so on, leads to the series of distinct dimensionless terms:

$$\frac{v}{TG},\ \frac{\rho Lv}{pT},\ \frac{\rho L^2}{\mu T},\ \frac{L\rho G}{p},\ \frac{G\rho L^2}{\mu v},\ \frac{pL}{\mu v} \tag{10}$$

Here the last three terms appear as numerical parameters not containing time explicitly. They probably could be used as characteristic numbers; this, however, has not become customary.

Since $\frac{vT}{L}$ is also dimensionless, it can be multiplied into the other dimensionless quantities. Multiplication with the first three numbers in (10) results in

$$\left.\begin{aligned}
&\frac{vT}{L}\cdot\frac{v}{TG} = \frac{v^2}{LG} \quad \text{which is Froude's number}\\
&\frac{vT}{L}\cdot\frac{\rho L v}{pT} = \frac{\rho v^2}{p} \quad \text{which is the reciprocal of Newton's number}\\
&\frac{vT}{L}\cdot\frac{\rho L^2}{\mu T} = \frac{\rho L v}{\mu} \quad \text{which is Reynolds' number}
\end{aligned}\right\} \qquad (11)$$

These are the three most widely known numerical parameters of general hydrodynamics and have been named after their first users. In the literature they are usually derived by philosophical arguments or long-winded dimensional deductions; here they follow naturally from the condition of unitary homogeneity of the fundamental differential equation.

2. The Dimensionless Products. Only four independent dimensionless products are possible, since the number of fundamental units $k = 3$ (only mechanical quantities are involved), the number of physical quantities, however, $N = 7$. Choose as these four products the three characteristic numbers and in addition $\frac{vT}{L}$; then there results as general type of solution in terms of dimensionless products

$$\psi\left[\frac{vT}{L}, \frac{v^2}{LG}, \frac{p}{v^2\rho}, \frac{v\rho L}{\mu}\right] = 0 \qquad (12)$$

That the four combinations are independent is easily seen from the fact that each contains one variable not present in any other product. Other choices could be made with the same degree of generality; however, any such set of dimensionless numbers must be derivable from the one chosen here by multiplication or division with dimensionless numbers only.

3. The Class Parameters. Since the phenomenon is properly described by the maximum number of independent dimensionless products, these can be chosen as class parameters for a whole series of problems represented by the same differential equation. The three numbers from (11) constitute the most widely used class parameters of hydrodynamics, and any solution can be expressed in terms of them. In conducting experiments they should be chosen as variables. If it is desired to express the solution in explicit form of a principal variable, the dimensional products have to be chosen so that only one contains this variable. Suppose it is desired to solve for p; then the third dimensionless product will be selected as principal class variable

$$\frac{p}{v^2\rho} = \phi\left[\frac{vT}{L}, \frac{v^2}{LG}, \frac{v\rho L}{\mu}\right] \qquad (12a)$$

where, of course, ϕ is not known but can be obtained by experiments. It follows

$$p = (v^2\rho)\cdot\phi\left[\frac{vT}{L}, \frac{v^2}{LG}, \frac{v\rho L}{\mu}\right] \qquad (13)$$

4. The Similarity Conditions. If equation 8 is transformed into a system with primed quantities and the proportionality factors are designated by s with a respective subscript

$$\left.\begin{matrix}
G = s_G\, G' & \rho = s_\rho\cdot\rho' & r = s_r\cdot r'\\
 & v = s_v\cdot v' & \\
p = s_p\cdot p' & \mu = s_\mu\cdot\mu' & t = s_t\cdot t'
\end{matrix}\right\} \qquad (14)$$

there follows

$$\left(\frac{s_v}{s_t}\right)\cdot\frac{\partial v'}{\partial t'} = (s_G)\cdot G' - \left(\frac{s_p}{s_\rho\, s_r}\right)\frac{1}{\rho'}\cdot\frac{\partial p'}{\partial z'} + \left(\frac{s_\mu\, s_v}{s_\rho\, s_r^2}\right)\cdot\frac{\mu'}{\rho'}\left(\frac{\partial^2}{\partial r'^2} + \frac{1}{r'}\cdot\frac{\partial}{\partial r'}\right)v'$$

and the three similarity conditions are

$$\left(\frac{s_v}{s_t\, s_G}\right) = 1, \ \left(\frac{s_p}{s_\rho\, s_r\, s_G}\right) = 1, \ \left(\frac{s_\mu\, s_v}{s_\rho\, s_r^2\, s_G}\right) = 1 \qquad (14a)$$

which must be satisfied to insure similar flow characteristics of two viscous fluids. If these conditions are satisfied, experimental results on one liquid can be utilized for another liquid without repetition of analysis or experiments.

5. For the Critical Values of the Class Parameters occurring in this example, see Art. 17, Section 6.

17. DIMENSIONAL ANALYSIS

In the literature on this subject much controversy is found relating to a proper and convincing basis of dimensional analysis. Mathematical proofs have been offered from principles of logic; however, there is no "principle" of similarity, or similitude, which would present a reasonable mathematical basis for the general dimensional analysis. Fundamentally, dimensional analysis is identical with the analysis of physical equations, and, in particular, with the analysis of physical differential equations. The information from dimensional analysis, therefore, is identical with that obtained from differential equations subject to unitary homogeneity. (See Art. 16.) The advantage of dimensional analysis is the more systematic approach in obtaining the class parameters and the similarity conditions, although it seems advisable to take a complete differential equation as the starting point in any case.

The Π Theorem

If z physical quantities Q_κ are known to be involved in a certain physical phenomenon, the mutual dependence, in unitary homogeneous form, must be expressible as a power product as has been shown on various occasions.* For example, the quantity Q_1 takes the form

$$Q_1 = Q_2^{\alpha_2} \cdot Q_3^{\alpha_3} \dots Q_z^{\alpha_z} \tag{15}$$

where the $\alpha_2, \alpha_3 \dots \alpha_z$ are definite and unique values which can be determined by dimensional analysis. This fact is based upon the fundamental and reasonable hypothesis of uniqueness of the results of physical measurements, no matter what units are used in measuring. Thus, for example, if $Q_1 = F$ represents force as expressed by mass, length, and time, it would be found $F = MLT^{-2}$ as a unitary homogeneous relation (see Art. 15) independent of the special units employed on the right-hand side. The unit of F, of course, is fixed by the condition of unitary homogeneity; any arbitrary choice of the unit of F would result in an additional numerical conversion factor.

On account of unitary homogeneity, the combination

$$\frac{Q_1}{Q_2^{\alpha_2} \cdot Q_3^{\alpha_3} \dots Q_z^{\alpha_z}} = \Pi \tag{15a}$$

is a numerical quantity and can be designated as a "dimensionless product." The number of possible independent dimensionless products is obviously $(z - k)$, if k is the number of independent fundamental units in the particular field. This result is the same as in the analysis of differential equations.

The most general form of a logical mathematical description of the phenomena studied must be some functional relation between the $(z - k)$ independent dimensionless product

$$\Psi\,(\Pi_1, \Pi_2, \dots \Pi_{z-k}) = 0 \tag{16}$$

This, of course, is but the typical solution of a differential equation in terms of class variables and class parameters, but now the functional form Ψ is not known and can be found only by experiment. The forms (15) and (16) are frequently referred to as the "Π theorem," and it is the object of dimensional analysis to find practical ways of obtaining the form (16) with greatest economy and least chance of erroneous reasoning.

The Method of Lord Rayleigh. Usually it is desired to learn the dependence of one physical quantity upon a number of other physical quantities which are supposed to enter into the problem or experiment. If the total number of quantities is z (including the physical constants), and the principal quantity chosen be Q_1, then (15) expresses the general physical relation for Q_1 according to the Π theorem. In general, the dimensions of the z quantities are not independent, but can be represented in terms of k fundamental dimensions, if the respective complete dimension system is composed of k fundamental dimensions. These can be chosen either from among the $Q_1 \dots Q_z$ themselves, or from any one of the more common dimension systems suitable for the particular field of physics. (See Arts. 3, 4, 5.) It is essential to use a complete dimension system in order to avoid ambiguity with respect to the dimensions of the physical constants. If the dimensional expressions are introduced into (15), and if then the exponents on both sides are equated there result exactly k conditions for the $(z - 1)$ exponents $\alpha_2 \dots \alpha_z$, permitting the expression of any k exponents in terms of the remaining $(z - 1 - k)$ indeterminate or "free" exponents.† The final expression gives then the desired physical quantity in terms of indeterminate powers of dimensionless products, but in an explicit form, which is the principal advantage of this method.

---

* J. L. Riabouschinsky, L'Aerophile, 1911; E. Buckingham, *Phys. Rev.*, Vol. 4, p. 345, 1914; F. London, *Phys. Zeits.*, Vol. 23, p. 262, 1922.

† Lord Rayleigh. *Nature*, Vol. 95, p. 66, 1915.

Example. To illustrate the method of Lord Rayleigh, assume the same example as treated in Art. 16. The differential equation gives all the parameters and variables that enter into the problem so that the list of physical quantities involved is (see the example in Art. 16):

$$v,\ t,\ G,\ \rho,\ p,\ \mu,\ l$$

Suppose it is desired to find the dependence of v on the other quantities; then the form corresponding to (15) is

$$v = t^{\alpha_1}\cdot G^{\alpha_2}\cdot \rho^{\alpha_3}\cdot p^{\alpha_4}\cdot \mu^{\alpha_5}\cdot l^{\alpha_6} \tag{17}$$

In the technical dimension system of mechanics there are three fundamental dimensions L, T, F. (See Art. 3.) It is convenient, in general, to write the dimensions of the various physical quantities in the form of a table.

Physical Quantities		t	G	ρ	p	μ	l	v
L	Exponents of Fundamental Dimensions	0	+ 1	− 4	− 2	− 2	+ 1	+ 1
T		+ 1	− 2	+ 2	0	+ 1	0	− 1
F		0	0	+ 1	+ 1	+ 1	0	0

Introducing the dimensions from this table into equation 17 and equating the dimensional exponents for L, T, and F gives the three linear simultaneous equations

$$\left.\begin{array}{rl} +\ \alpha_2 - 4\alpha_3 - 2\alpha_4 - 2\alpha_5 + \alpha_6 & = +1 \\ +\ \alpha_1 - 2\alpha_2 + 2\alpha_3 \qquad + \alpha_5 & = -1 \\ +\ \alpha_3 + \alpha_4 + \alpha_5 & = 0 \end{array}\right\} \tag{18}$$

Since there are six unknowns, three of the exponents will remain indeterminate. Suppose α_1, α_3, and α_6 are chosen for some reason to be left indeterminate; then from (18)

$$\left.\begin{array}{l} \alpha_2 = +\,1 + 2\alpha_3 - \alpha_6 \\ \alpha_4 = -\,1 - 3\alpha_3 + 2\alpha_6 + \alpha_1 \\ \alpha_5 = +\,1 + 2\alpha_3 - 2\alpha_6 - \alpha_1 \end{array}\right\} \tag{18a}$$

so that the velocity can be written, properly collecting terms with the same exponents,

$$v = \frac{\mu G}{p}\cdot\left[\frac{Tp}{\mu}\right]^{\alpha_1}\cdot\left[\frac{G^2\,\rho\mu^2}{p^3}\right]^{\alpha_3}\cdot\left[\frac{Lp^2}{G\mu^2}\right]^{\alpha_6} \tag{19}$$

The advantage of having v explicitly given is obvious. Each one of the three independent dimensionless products is a combination of some of the dimensionless products in (10), as can be shown easily. Instead of using the indeterminate exponents α_1, α_3, α_6, any arbitrary function of the dimensionless products would be a more general expression.

$$v = \frac{\mu G}{p}\cdot\psi\left[\frac{Tp}{\mu},\ \frac{G^2\,\rho\mu^2}{p^3},\ \frac{Lp^2}{G\mu^2}\right] \tag{20}$$

In the same way the dependence of p on the other quantities involved could be computed, and the result would be similar to (13); the special form would depend upon the particular choice of the $(z - 1 - k)$ free exponents, but could always be transformed into the form (13) by multiplying the dimensionless products by dimensionless numbers from (10).

The Method of E. Buckingham.* Suppose that the total number of physical quantities involved in a problem is z (including the physical constants), and the number of independent fundamental dimensions, necessary for the particular field of physics to which the problem belongs, is k; then k of the z quantities, which are dimensionally independent, are arbitrarily chosen as principal quantities. If Q_1 to Q_k are these principal quantities and Q_{k+1} to Q_z the secondary quantities, $(z - k)$ independent dimensionless products can be formed by multiplying indeterminate powers of the principal quantities successively with one of the secondary quantities and equating the total dimensions to zero, as, for example,

$$[\Pi_1] = [Q_1^{\alpha_1}\cdot Q_2^{\alpha_2}\ldots Q_k^{\alpha_k}\cdot Q_{k+1}] = 1 \tag{21}$$

If now the dimensions of Q_{k+1} in terms of the dimensions of the principal quantities are introduced, k linear relations for the exponents $\alpha_1 \ldots \alpha_k$ result so that all the exponents can be determined. In this way $(z - k)$ independent dimensionless products are obtained directly; their special form depends entirely upon the choice of the principal quantities. The advantage of this method lies in the simple form of the equations which determine the exponents of the principal quantities; it is also possible to solve explicitly for any single quantity, if it is not a principal quantity.

---

* E. Buckingham, *Phys. Rev.*, Vol. 4, p. 345, 1914; *Phil. Mag.* (6), Vol. 42, p. 696, 1921.

Example. To illustrate the method by E. Buckingham, and to be able to compare it with the other methods, assume the same example as before, with the physical quantities

$$v,\ t,\ G,\ \rho,\ p,\ \mu,\ l$$

In choosing the three principal quantities it must be kept in mind that they will appear in all dimensionless products as factors. Suppose l, ρ, and v be chosen here; using the technical mechanical dimension system, the dimensions of all the quantities are again given in the table on page 3–42. Grouping the dimensional expressions for the dimensionless product $[l^{\alpha_1}\rho^{\alpha_2}v^{\alpha_3}\cdot t] = 1$ in a table

	l^{α_1}	ρ^{α_2}	v^{α_3}	t
$[L]$	$+\alpha_1$	$-4\alpha_2$	$+\alpha_3$	0
$[T]$	0	$+2\alpha_2$	$-\alpha_3$	$+1$
$[F]$	0	$+\alpha_2$	0	0

gives immediately the resulting equations

$$\left.\begin{aligned} +\alpha_1 - 4\alpha_2 + \alpha_3 + 0 &= 0 \\ +2\alpha_2 - \alpha_3 + 1 &= 0 \\ +\alpha_2 \qquad + 0 &= 0 \end{aligned}\right\}$$

from which $\alpha_2 = 0, \quad \alpha_3 = +1, \quad \alpha_1 = -1$

so that the product becomes $\dfrac{vT}{l}$. Similar tables with t replaced successively by G, p, and μ, give the other three dimensionless products as $\dfrac{lG}{v^2}$ (the reciprocal of Froude's number), $\dfrac{p}{\rho v^2}$ (Newton's number), and $\dfrac{\mu}{l\rho v}$ (the reciprocal of Reynolds' number). The general solution, therefore, is a functional relation of the four dimensionless products

$$\psi\left[\frac{vT}{l}, \frac{lG}{v^2}, \frac{p}{\rho v^2}, \frac{\mu}{l\rho v}\right] = 0 \tag{22}$$

which is identical with the solution obtained in (12) from the analysis of the differential equation.

Note on the Application of Dimensional Analysis

It has been customary to surround dimensional analysis with an air of intuitive invention. The comparison of differential equation analysis and dimensional analysis has shown that both are based upon the condition of unitary homogeneity of physical equations. It is obvious, therefore, that dimensional analysis must lead to the same result as the analysis of differential equations, if it is properly used. The chief advantage of dimensional analysis is the fact that it deals with the class variables and parameters and thus reduces the number of variable quantities from z to $(z - k)$, if z is the number of physical quantities and k the number of fundamental dimensions. It can serve as a guide for experiments and gives the conditions of similarity without necessitating a complete solution of the problem. As a basis for model experiments it is extremely valuable. (See Art. 18.)

In applying dimensional analysis, care has to be taken to include all physical quantities which might be involved in the problem. It seems best to start from an approximate differential equation as the expression of "balance" of forces, or energies, or what not, and to include all dimensional physical constants. If any system of $z - k$ independent dimensional products has been found, other systems can be obtained by combination of two or more numerical parameters into new dimensionless products. It is not possible to replace differential equation analysis by dimensional analysis, since the latter never will give the complete form of the solution of a problem.

Dimensional analysis, as well as differential equations, have certain ranges of validity; if experiments do not check the results of an analysis, it might serve as an indication that the problem is incompletely stated and more physical quantities should be included. Neither differential equations nor dimensional analysis can ever lead to new physical constants; these are defined by the fundamental hypotheses.

18. THEORY OF MODELS

The possibility of similarity between various systems of even wholly unrelated fields suggests the exploration of phenomena by means of "models" of either enlarged or reduced scale, or by means of analogies from a different field. Just as similarity cannot be an absolute quality, but is defined as the approximate state of two systems (see Art. 16), so can a model be only an approximate reproduction of the original scale phenomenon; the approximation can, of course, be quite close over certain ranges of the main variables. It is essential, in the use of models, to state definitely the properties to be modeled and to restrict conclusions to the quantities included in the similarity considerations.

The Scale Factors. If the same differential equation is assumed to hold for two different problems of the same field, then similarity exists between the phenomena described by the differential equation. Any one term in the differential equation for *case 1* may be of the form

$$(Q_a^{n_1} \cdot Q_b^{n_2} \cdot Q_c^{n_3} \ldots) \frac{d^\nu y}{dx^\nu}$$

where the factor in parentheses is the coefficient of the νth differential. For *case 2* this term will become

$$(\overline{Q}_a^{n_1} \cdot \overline{Q}_b^{n_2} \cdot \overline{Q}_c^{n_3} \ldots) \frac{d^\nu \overline{y}}{d\overline{x}^\nu}$$

and the new physical quantities (physical constants or variables) may be related to the former ones by the expressions

$$\left.\begin{array}{c} \overline{Q}_a = s_a Q_a, \quad \overline{Q}_b = s_b Q_b, \quad \overline{Q}_c = s_c Q_b \ldots \\ \overline{y} = s_y \cdot y, \quad \overline{x} = s_x \cdot x. \end{array}\right\} \tag{23}$$

Suppose now that case 2 shall be used as a model for case 1. Each physical quantity in the model must then take a definite ratio to the same quantity in the original, and the proportionality factors (23) can be considered as *scale factors*, specifying the relations between the model and the original. Obviously, there are as many scale factors as there are physical quantities. It is not possible to choose all the scale factors arbitrarily.

Model Rules. In order to be permitted to use case 2 as a model of case 1, the conditions of similarity must be satisfied. As shown in Art. 16, the similarity conditions require, using (23) above,

$$(s_a^{n_1} \cdot s_b^{n_2} \cdot s_c^{n_3} \ldots) \frac{s_y}{s_x^\nu} = k, \tag{24}$$

k is the same constant for all the terms, so that the numerical values in the differential equations for both cases are identical.

If there are q terms in the differential equation, there will be q conditions of the type (24) or $(q - 1)$ mutual relations between the scale factors. These are called *the model rules*, as they specify size, shape, and physical properties of the model (as applied forces, densities, viscosities, and so on). The model rules depend entirely on the differential equation chosen to represent the phenomenon.

Fundamental and Dependent Scale Factors. The scale factors which can be chosen arbitrarily are called *fundamental scale factors*. The number of fundamental scale factors is identical with the number of fundamental dimensions necessary for a complete dimension system in the particular field of physics to which the problem belongs. This can be seen from the general differential equation; if z physical quantities are involved, and q terms make up the differential equation, then $(z - q + 1)$ fundamental dimensions are required. (See Art. 15.) But there are also z scale factors, which have to satisfy, according to (24), $(q - 1)$ relations, so that $(z - q + 1)$ fundamental scale factors remain which can be chosen arbitrarily. All the other scale factors follow by means of the model rules, they are dependent, and cannot be chosen freely.

Model Rules from Dimensional Analysis. Dimensional analysis leads to a description of a physical phenomenon in terms of dimensionless products which are identical with, or can be easily transformed into, the class parameters of the analysis of differential equations. (See Art. 17.) Similarity in terms of dimensional analysis exists only if the dimensionless products have the same numerical values for both the model and the original. If any one of the dimensionless products Π_ν for *case 1* is given by

$$\Pi_\nu = (Q_1^{\alpha_1} \cdot Q_2^{\alpha_2} \ldots Q_k^{\alpha_k}) \cdot Q_{k+\nu}$$

and for *case 2* by

$$\overline{\Pi}_\nu = (\overline{Q}_1^{\alpha_1} \cdot \overline{Q}_2^{\alpha_2} \ldots \overline{Q}_k^{\alpha_k}) \cdot \overline{Q}_{k+\nu}$$

and if there are the scale relations

$$\overline{Q}_1 = s_1 Q_1, \quad \overline{Q}_2 = s_2 Q_2 \ldots \quad \overline{Q}_{k+\nu} = s_{k+\nu} Q_{k+\nu}$$

then $\Pi_\nu = \overline{\Pi}_\nu$ only if

$$(s_1^{\alpha_1} s_2^{\alpha_2} \ldots s_k^{\alpha_k}) \cdot s_{k+\nu} = 1 \tag{25}$$

Since there are $(z - k)$ independent dimensionless products, the z scale factors will be related by $z - k$ relations of the type (25), so that the number of free or fundamental scale factors is k, the same as the number of fundamental dimensions. The relations (25) are called the model rules and are identical with the relations (24). They can be *conveniently obtained* by replacing in the dimensionless products all the physical quantities by their respective scale factors and equating to unity the expressions thus obtained.

Example. In order to illustrate the application of the theory of models, it will be chosen to represent the flow of water through a large pipe by the flow of mercury through a model pipe of one-tenth the diameter of the original. Using dimensional analysis, the problem is the same as treated above in Art. 17. As a problem of hydrodynamics, $k = 3$ fundamental dimensions, and, therefore, $k = 3$ fundamental scale factors are necessary. The ratio of the linear dimensions is given by $s_l = 0.1$; the ratio of the densities is $s_\rho = 13.6$, and the ratio of the viscosities can be assumed approximately as $s_\mu = 1.5$. The four dimensionless products are given by equation 22, so that the scale factors have to satisfy the conditions

$$\frac{s_v\, s_t}{s_l} = 1, \quad \frac{s_l\, s_G}{s_v^2} = 1, \quad \frac{s_p}{s_\rho\, s_v^2} = 1, \quad \frac{s_\mu}{s_l\, s_\rho\, s_v} = 1$$

from which the four dependent scale factors follow as

$$s_v = 1.103, \quad s_G = 12.16, \quad s_p = 16.54, \quad s_t = 0.0908$$

which means that the velocity of the mercury flow must be 1.103 of that of water, and the time scale approximately 0.0908 of that of water, and the force, per unit of mass, acting upon the mercury must be made 12.16 times that for water.

* Section 4 was prepared from material in previous handbooks published by John Wiley and Sons.

The editor and author wish particularly to acknowledge the contributions of Professors C. H. Burnside and E. R. Maurer. Much of their original work in Merriman's Civil Engineers' Handbook and Peele's Mining Engineers' Handbook was used in the preparation of this Section.

THEORETICAL MECHANICS

1. DEFINITIONS

Mechanics is that branch of *science* which treats of forces and motion.

Statics is that branch of *mechanics* which deals with the equilibrium of forces on bodies *at rest* (or moving at a uniform velocity in a straight line).

Kinematics is that branch of *mechanics* which deals with the motion of bodies without consideration of the character of the bodies or of the influence of forces upon their motion. It considers only concepts of *geometry* and *time.*

Kinetics (or Dynamics) is that branch of *mechanics* which deals with the effect of unbalanced external forces in *modifying the motion* of bodies.

Mass and Weight, in the *gravitational system of units* employed by English engineers, are related by the formula $W = Mg$, where W = weight, M = mass, and g = acceleration due to gravity. For a thorough discussion of these terms, see Section 3, Physical Units and Standards.

Force is that which changes or tends to change the state of rest or motion of a body.

Inertia is that property of a body by virtue of which it tends to continue in the state of rest or motion in which it may be placed, until acted on by some force.

Reaction is that *equal and opposite force* exerted by a body in opposing another force acting upon it.

Newton's Laws of Motion. *First Law.* If a body is at rest, it will remain at rest, or if in motion, it will move uniformly in a straight line, until acted on by some force.

Second Law. If a body is acted on by several forces, it will obey each as though the others did not exist, and this whether the body is at rest or in motion. Change of the motion of a body is proportional to the force and to the time during which the force acts, and is in the same direction as the force.

Third Law. If a force acts to change the state of a body with respect to rest or motion, the body will offer a resistance equal and directly opposed to the force. Or, to every action there is opposed an equal and opposite reaction.

Special Terms such as **hydrostatics, aerodynamics,** etc., are used to denote the theory of statics as applied to *liquid bodies*, the theory of dynamics as applied to *gaseous bodies*, etc. **Mechanics of materials** considers, in addition to *external forces*, the *internal forces* or *stresses* between molecules of a body. Subjects of these types are covered in other sections of this handbook. The present section on *mechanics* is confined, in general, to the discussion of motion of, and *external forces* applied to, *rigid bodies.*

STATICS

2. GRAPHICAL REPRESENTATION AND CLASSIFICATION OF FORCES

Graphical Representation of Force

A Force is completely specified by its *magnitude, direction,* and *point of application.* The word **sense** as applied to a force refers to one of the two directions along the line of action of the force. The effect of any force applied to a rigid body at rest is the same, no matter where in its own line of action the force is applied. This is known as the principle of the **transmissibility of force.** A force may be represented graphically in magnitude and direction by a straight line drawn parallel to its line of action, the length being proportional to the magnitude of the force; its sense is indicated by an arrowhead placed on the line. The English engineers' unit of force is the pound, or the earth's pull on a mass of 1 lb. A drawing which indicates the lines of action of the various forces acting on a machine or structure

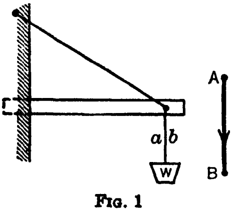

FIG. 1

is called a **space diagram**; one in which vectors are drawn to represent the magnitudes and directions of the forces is a **vector diagram.** A force is indicated on a space diagram by two lower-case letters placed on opposite sides of the line of action of the force; the vector, representing its magnitude and direction, by the same capital letters placed at the ends. Thus, in Fig. 1, AB represents the magnitude and direction of the force W, and ab its action line. The vector being read as AB indicates a downward sense; read as BA, an upward sense.

Classification of Systems of Forces

A System of Forces consists of any number of forces taken collectively.

Classification of Systems of Forces is made according to the arrangement of their action lines. If the action lines lie in the same plane the system is **coplanar,** otherwise **noncoplanar.** If they pass through the same point the system is **concurrent,** otherwise **nonconcurrent.** If two or more forces have the same action line they are **collinear.** A system of two equal forces, parallel, opposite in sense, and having different action lines is **a couple.** Two or more forces equivalent to a single force are **components** of the single force. **Resolution** is the operation of replacing a single force by a system of components. The single force is the **resultant** of its components. In general, the resultant of a system of forces is the simplest equivalent system. This may be a *single force*, a *single couple*, or a *noncoplanar force and couple* (or *two skewed forces*). When the resultant is a single force the **equilibrant** is a force equal in magnitude, having the same line of action but opposite sense. **Composition** is the operation of replacing a system of forces by its resultant.

3. COMPOSITION AND RESOLUTION OF CONCURRENT FORCES

Composition of Two Concurrent Forces *

Parallelogram Law. If magnitudes, lines of action, and senses of two concurrent forces acting on a rigid body are represented by OA and OB (Fig. 2), the magnitude, line of action, and sense of their resultant are represented by the diagonal OC of the parallelogram $OABC$. The points of application of the forces may be anywhere on the body in the lines OA, OB, and OC, or their extensions. The arrowheads on the lines OA, OB, and OC all point toward or all away from the point of concurrence O.

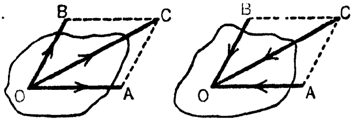

FIG. 2

Triangle Law. This law follows directly from the parallelogram law. If in the triangle ABC (Fig. 3*a*) AB and BC represent two concurrent forces in magnitude, direction, and sense, AC will represent their resultant in magnitude, direction, and sense; its action line will be ac through the point of concurrency, parallel to AC. It should be noted that the arrowheads on the sides AB and BC are **confluent** (point the same way around) but the arrowhead on AC is not confluent with the others. Also, the point of concurrency need not necessarily be located in or on the body but may be outside it.

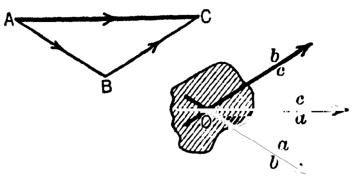

FIG. 3*a*

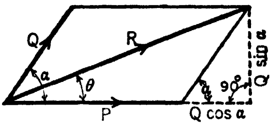

FIG. 3*b*

The resultant may be found **algebraically** thus: In Fig. 3*b*, let α be the angle between the action lines of forces P and Q, and θ the angle between R and P. Then, $R^2 = P^2 + Q^2 + 2PQ \cos \alpha$, and $\tan \theta = \dfrac{Q \sin \alpha}{P + Q \cos \alpha}$. If $\alpha = 90°$, $R^2 = P^2 + Q^2$, and $\tan \theta = Q/P$.

---

* It is evident that a pair of concurrent forces and their resultant are necessarily *coplanar*.

Resolution into Two Concurrent Forces *

A Force May Be Resolved into an infinite number of pairs of components by constructing different triangles as in Fig. 4*a*. The action lines of the components must be concurrent at a point on the action line of the force. A common problem is to resolve a force into *rectangular components* (often called resolved parts). In Fig. 4*b*, AB and BC are a set of rectangular components of the force P. Expressed *algebraically*, $AB = P \cos \alpha$ and $BC = P \sin \alpha$. For rectangular components, the resolved part of a force along any line equals the magnitude of the force times the cosine of the angle between the lines of action of the force and its component. Action lines of the components are concurrent on the space diagram at some point on ac, as at D or D'.

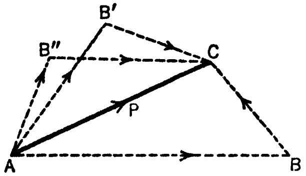

FIG. 4*a*

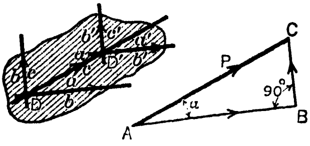

FIG. 4*b*

Composition of More than Two Coplanar Concurrent Forces †

Graphic Method. In Fig. 5, consider body G acted on by the four forces shown. Construct a **force polygon** as follows: Plot AB parallel to ab, and scale it to represent 60 lb.; from B plot BC parallel to bc, and scale it to represent 80 lb.; in like manner plot CD and DE, so that the arrows lead *confluently* from A to E. The resultant of the system is AE in magnitude and sense and equals 114 lb. Its action line is ae. The resultant will be the same regardless of the order in which the forces are plotted. Note particularly that the resultant is not confluent with the component forces.

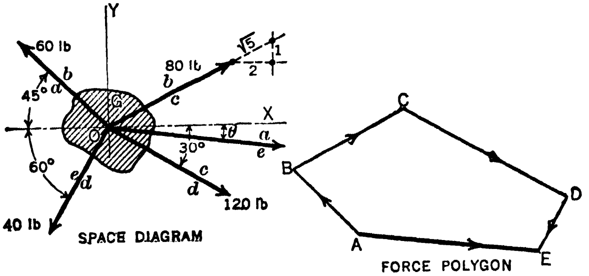

FIG. 5

Algebraic Method. Choose rectangular axes OX and OY. Referring to Fig. 5, resolve each force into its x and y components, considering components acting upward or to the right as positive, and those acting downward or to the left as negative. Arrange the results in tabular form, placing the forces in the first column, the x components in the second, and the y components in the third. ΣF_x = algebraic sum of x components, and ΣF_y = algebraic sum of y components.

F, lb	F_x, lb	F_y, lb
$ab = 60$	$-60 \times 0.707 = -42.4$	$+60 \times 0.707 = +42.4$
$bc = 80$	$+80 \times 2/\sqrt{5} = +71.4$	$+80 \times 1/\sqrt{5} = +35.7$
$cd = 120$	$+120 \times 0.866 = +104$	$-120 \times 0.5 = -60$
$de = 40$	$-40 \times 0.5 = -20$	$-40 \times 0.866 = -34.6$
	$\Sigma F_x = +113$	$\Sigma F_y = -16.5$

---

* It is evident that a pair of concurrent forces and their resultant are necessarily *coplanar*.

† The composition of two concurrent forces is simply a special case of this more general treatment.

Then $R = \sqrt{\Sigma F_x^2 + \Sigma F_y^2} = \sqrt{13{,}041} = 114$ lb. Sense is downward and to the right (Fig. 6). Tan $\theta = \dfrac{\Sigma F_y}{\Sigma F_x} = -0.146$; $\theta = -8°\,20'$.

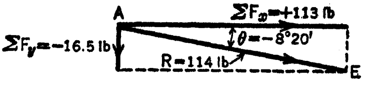

Fig. 6

Resolution into More than Two Coplanar Concurrent Forces

This type of problem has relatively little practical value. The resolution can be accomplished, however, by employing the force polygon to reverse the process of composition in a manner similar to that employed in the important special case discussed above of resolution into two concurrent forces. An infinite number of force systems is possible for any given number of the component concurrent forces.

Composition of Three Rectangular Noncoplanar Concurrent Forces

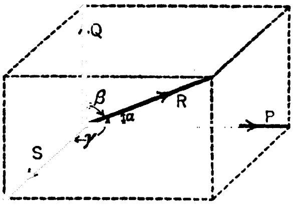

Fig. 7

Parallelepipedon Law.* Consider the three rectangular forces, P, Q, and S (Fig. 7). On these forces construct to scale a parallelepiped. The resultant of the system is represented in magnitude and direction by the diagonal; its value is $R = \sqrt{P^2 + Q^2 + S^2}$. Its direction cosines with respect to the axes are: $\cos\alpha = P/R$, $\cos\beta = Q/R$, and $\cos\gamma = S/R$.

Resolution into Three Rectangular Noncoplanar Concurrent Forces

A force F can be resolved into a set of three rectangular noncoplanar concurrent forces by *reversing* the process of composition described in the preceding paragraph. Thus, referring to Fig. 7:

$$P = R\cos\alpha;\quad Q = R\cos\beta;\quad S = R\cos\gamma$$

Composition of Any Number of Concurrent Forces †

This is the most general case of composition of concurrent forces and therefore is applicable also, of course, to the simpler cases previously discussed.

Let the forces be specified with respect to three rectangular axes passing through the point of concurrency: (*a*) Resolve each force into components along the X, Y, and Z axes; (*b*) find the algebraic sums of the x, y, and z components, and indicate them by ΣF_x, ΣF_y, and ΣF_z; (*c*) find the resultant of these three partial resultants by the parallelepipedon law; its value is $R = \sqrt{\Sigma F_x^2 + \Sigma F_y^2 + \Sigma F_z^2}$; its direction angles are $\alpha = \cos^{-1}\dfrac{\Sigma F_x}{R}$; $\beta = \cos^{-1}\dfrac{\Sigma F_y}{R}$; $\gamma = \cos^{-1}\dfrac{\Sigma F_z}{R}$.

Nature of Resultant of Concurrent Forces

The Resultant of any system of *concurrent forces* which are not in equilibrium is a *single force.*

4. MOMENTS AND COUPLES

Moment (or Torque) of a Force about a Point

Moment or Torque of a force about a point is the product of the force magnitude and the distance from the point to its action line. This perpendicular distance is called the *arm* of the force, and the point is the *origin or center of moments.* The product is the measure of the rotational tendency of the force. The name of the unit of moment is a combination of the names of force and distance units, as foot-pound, inch-ton, etc. (Some writers use lb-ft as a unit of moment of a force to distinguish from ft-lb as the unit of work or energy, similar distinction being made for the other units.)

---

* The *parallelepipedon law* applies also if the three forces are not rectangular. In such cases, however, it is not practicable to obtain *directly* the value of the resultant either graphically or algebraically. A better method of solution for problems of this nature is given in the second succeeding paragraph.

† As a matter of academic interest, although of little practical value, the resultant of any number of noncoplanar concurrent forces may be represented graphically by extending the principles of the *plane* force polygon to apply to a *space* or *skew* force polygon.

To facilitate computations, the moment of a force with respect to a point is frequently computed by taking the algebraic sum of the moments of two rectangular components of the force with respect to that point; and it will often be convenient to resolve the force so that one of the components will act through the origin of moments, thus making that component have no moment.

Moment (or Torque) of a Force about a Line (or Axis)

At any point on its action line, resolve the force into two rectangular components, one being parallel to the axis. The product of the perpendicular component and the perpendicular distance to its line of action from the axis is the *moment* of the given force about the axis. Thus (Fig. 8), $P \sin \alpha$ is the component parallel to the axis, and it has no turning effect. All the moment or turning effect is caused by the perpendicular component, and its value is $P \cos \alpha \times OE$, OE being the perpendicular distance between the axis and the parallel plane $ABCD$.

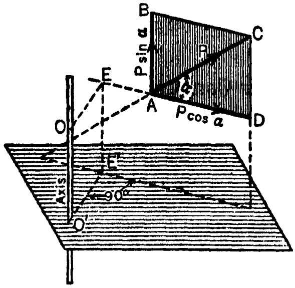

FIG. 8

To facilitate computations, the moment of a force with respect to an axis is frequently computed by resolving the force into three rectangular components, one being parallel to the axis, the other two perpendicular to it; then the moment of the given force equals the algebraic sum of the moments of the two perpendicular components. If the resolution is made so that one of the perpendicular components cuts the axis, the moment of the given force equals the moment of the other perpendicular component.

Principle of Moments

For a Point. The moment of the resultant of any coplanar forces (not necessarily concurrent) about a point in their plane equals the algebraic sum of the moments of those forces about the point. Thus (Fig. 9), R is the resultant of P and Q, and $R \times r = P \times p - Q \times q$. Moments tending to produce counterclockwise rotation of a body are usually considered positive, and clockwise negative. Thus, in Fig. 9, the moment of force Q about $O = -Qq$.

It is evident that the moment of a force passing through the origin of moments is zero.

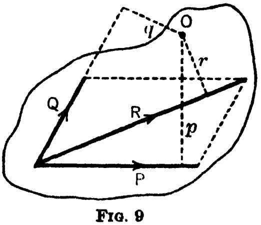

FIG. 9

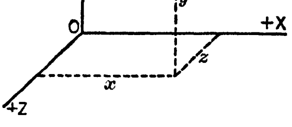

FIG. 10

For an Axis. The moment of the resultant of any forces (not necessarily either coplanar or concurrent) about a line equals the algebraic sum of the moments of those forces about the line. Thus (Fig. 10), R is the resultant of the three rectangular forces P, Q, and S. Moment of R about axis $X = S \times y - Q \times z$. P contributes nothing to the moment sum, as it is parallel to the axis of moments. Usually in such a case, counterclockwise moment is called positive and clockwise negative, the observer looking toward the origin O, from the positive ends of the axes. Thus, Q has positive moment about axis Z, but negative moment about axis X.

It is evident that the moment of a force parallel to or intersecting the axis of moments is zero.

Couples

Nature of Couples. Two equal and parallel forces of opposite sense are called a *couple.* The tendency of a couple is to produce rotation only. Since a couple has no single resul-

tant, no single force can balance it. To prevent the rotation of a body acted upon by a couple, the application of two other forces is required, forming a second couple.

The *arm* of a couple is the perpendicular distance between the lines of action of the forces. The *moment* of a couple is constant and independent of the origin of moments; it is equal to one of the forces times the arm of the couple. Its sense is positive or negative according as rotational tendency is counterclockwise or clockwise. Couples of equal moments, in the same or parallel planes, are *equivalent* and may be replaced one by the other. Further, the *center of rotation* for a couple may be anywhere in its plane. Hence, a couple may be turned about in its own plane or moved to a parallel plane or replaced by another couple (having an arm of any given length but the same moment) without altering its effect on a rigid body.

Resultant of Couples. The resultant of any number of coplanar couples or of couples in parallel planes is a couple. Its moment and sense equal the algebraic sum of the moments of the component couples.

A couple may be represented by a **vector.** The length of the vector to scale represents the magnitude of the moment; it is drawn perpendicular to the plane of the couple from *any origin*, and an arrow is placed on it to represent the way in which the couple would cause a right-hand screw to advance. The resultant of any number of couples (in oblique or parallel planes) is a couple. The composition is effected by simply adding the vectors representing the couples in a manner analogous to the method of "Composition of Any Number of Concurrent Forces" as previously described in this section. The resultant vector defines the resultant couple.

Composition of Single Force and Couple. A *single force and couple in the same plane (or parallel planes)* may be composed into *another single force* equal and parallel to the original force, at a distance from it equal to the moment of the couple divided by the magnitude of the force and so situated that the moment of the resultant about the point of application of the original force is of the same sign as the moment of the couple. The couple may be brought into the position shown in Fig. 11. The resultant of P, $-Q$, and Q is $R(=P)$ acting in a line through point C so that $(P - Q) \times AC = Q \times BC$. From this it follows that

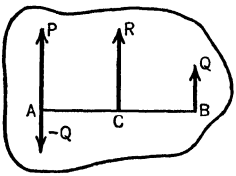

FIG. 11

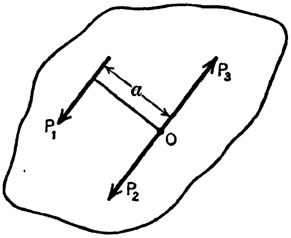

FIG. 12

$$AC = \frac{Q(AC + BC)}{P} = \frac{\text{moment of couple}}{P}$$

Resolution into Single Force through Chosen Point and Couple. A *single force* may be resolved into *another single force acting through a chosen point and a couple* (the new force being equal and parallel to the original force). In Fig. 12, P_1 is the given force and O the chosen point. Through O apply a pair of forces, opposite in sense, equal and parallel to P_1. As P_2 and P_3 balance, no change is produced in the motion of the body due to the addition. P_1 and P_3 constitute a couple of moment $= P \times a$, which is the same as moment of P_1 about O; and P_2 is a force just like P_1, but acting through the chosen point O.

5. COMPOSITION OF NONCONCURRENT FORCES

Composition of Coplanar Nonparallel Nonconcurrent Forces

Graphic Method (1): String (or Funicular) Polygon. This method involves the resolution of each force into two components in a certain way and the subsequent composition of the components to determine the resultant. Thus, to find the resultant of the three forces *ab*, *bc*, and *cd* acting on the body in Fig. 13, draw a force polygon, as *ABCD*, for the given forces; resolve *AB* into *AO* and *OB*; *BC* into *BO* and *OC*, etc., *O* having been taken anywhere; all components except the first and last occur in pairs and the forces of each pair are equal and opposite, thus *OB* and *BO*, *OC* and *CO*, etc.; choose the action lines of these components so that those of any one pair shall be collinear; thus, insert the components of AB at pleasure as at oa and ob, the components of BC so that the component BO shall act in ob, and hence the component OC in oc, etc.; thus the pairs of components consisting of equal, collinear, and opposite forces each balance, leaving only the first and last components AO and OD acting in ao and od; and their resultant (which is also the resultant of the given forces) is AD (magnitude and direction) ad (action line). The point O (Fig. 13) is called the **pole**, lines OA, OB, OC, etc., are **rays**; oa, ob, oc, etc., **are strings**, and all the strings constitute the **string (or funicular) polygon** for the forces. This polygon is also called "link," and "equilibrium polygon," the last being especially appropriate when the given forces are in equilibrium. The object in its construction is to locate one point on the action line of the resultant (or the length of arm to be used with the first and last rays of the force polygon if the resultant is a couple; see example in a later paragraph). The part of the drawing which represents the body and the lines of action of the forces is the *space diagram*; that representing force magnitudes, the *force polygon*. If the force polygon closes, the resultant is in general a couple, the forces of the couple acting in the first and last strings of the string polygon, the magnitude of the forces being represented by the corresponding ray. If in addition to the force polygon closing, the first and last strings coincide, the string polygon is closed and the resultant vanishes. If the force polygon does not close, the first and last strings of the string polygon may still happen to have the same line of action but the forces along them will not be equal. The resultant is then the force (in magnitude and direction) required to close the force polygon, and its line of action is that of the coinciding first and last strings.

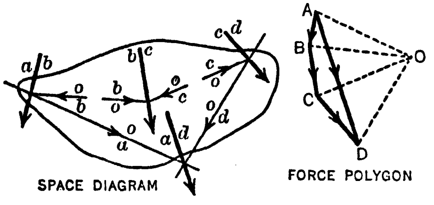

Fig. 13

Graphic Method (2): Triangle Law. If the forces are not parallel and not nearly parallel, find the resultant R_1 of any two forces by the *Triangle Law*, then the resultant R_2 of R_1 and a third force, etc., until all the forces have been compounded. If the forces are parallel or nearly so, the method just explained fails because the lines of action of the several resultants cannot be determined readily on account of inaccessible intersections. In such cases, Graphic Method (1) is the only *graphic* method which can be used.

Algebraic Method. Compute the algebraic sums of the x and y components of the forces (ΣF_x and ΣF_y) and the algebraic sum of the moments of the forces (or of their components if more convenient, the result being the same), with respect to any origin O in their plane (ΣM). Then the resultant $R = \sqrt{(\Sigma F_x)^2 + (\Sigma F_y)^2}$, its angle with the x axis $= \tan^{-1} (\Sigma F_y)/(\Sigma F_x)$, and its arm with respect to O is $a = (\Sigma M)/R$. The general direction of R is apparent from the directions of its components ΣF_x and ΣF_y; a must be measured in such a direction from O that the sign of the moment of R will be the same as that of ΣM. If $\Sigma F_x = \Sigma F_y = 0$, the resultant is in general a couple whose moment $= \Sigma M$. If $\Sigma M = 0$ also, the resultant vanishes.

Composition of Coplanar Parallel Forces *

Graphic Method. If the forces are parallel or nearly so, *Graphic Method* (1) as described under the preceding heading for use with nonparallel forces may be used. *Graphic Method* (2) is not practical.

Using Graphic Method (1), if the force polygon does not close, the resultant is a single force. If it closes, the resultant is in general a couple. As an illustration of the latter, consider the four parallel forces in Fig. 14. The force polygon begins at A and ends at E, the same point; hence the resultant is not a single force (this is called a closed force polygon). Construct the funicular polygon as before. The first and last strings, ao and oe, being parallel, do not intersect.† The forces acting in those lines, AO and OE, being equal and opposite in sense, form a couple. Hence the resultant of the system is a couple whose moment is $AO(=OE) \times MN$. The *sense*, by inspection of the space diagram, is *clockwise*.

---

* Parallel forces are by nature *nonconcurrent*.

† It must be clearly understood that the fact that the forces are parallel and the fact that the first and last strings are parallel in the particular system illustrated in Fig. 14 have no bearing on each other. The first and last strings may or may not be parallel (or coincident) when the forces *either* are or are not parallel depending simply upon whether or not the resultant force vanishes (or happens to coincide in line of action with *both* of the strings).

If in addition to the force polygon closing, the first and last strings coincide, the string polygon is closed and the resultant vanishes.

Algebraic Method. This is a special case of that described under a preceding heading for use with nonparallel forces. The resultant $R = \Sigma F$. Its arm $a = (\Sigma M)/R$ and must be measured in such a direction from the origin of moments that the sign of the moment of R will be the same as that of ΣM.

If $\Sigma F = 0$, the resultant is in general a couple. If $\Sigma M = 0$ also, the resultant vanishes.

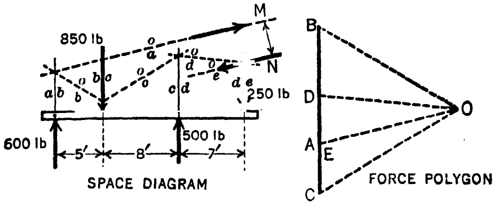

Fig. 14

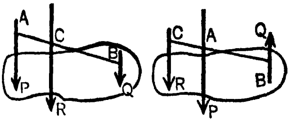

Fig. 15

Simple Cases. When only two parallel forces are involved, their resultant (if a force) may be located more quickly by application of the following simple theorem based on Fig. 15. If P and Q act in the same direction, R cuts any line AB internally, and if P and Q are opposite, then externally on the side of the larger force; and in each case the segments of AB are inversely proportional to P and Q; that is, $AC/BC = Q/P$.

Composition of Noncoplanar Parallel Forces *

Graphic Methods are not advantageous in general for use in determining resultants of noncoplanar nonconcurrent force systems. Therefore only the algebraic method will be discussed.

Algebraic Method. Give to the forces F acting in the same direction one sign and to the others the opposite sign; then the resultant $R = \Sigma F$, the sense of R being indicated by the sign of ΣF. Next compute the sums of the moments of the forces with respect to two rectangular axes (x and y, say) perpendicular to the forces; call these sums ΣM_x and ΣM_y, and the arms of R with respect to those axes respectively a_x and a_y; then $a_x = (\Sigma M_x)/R$ and $a_y = (\Sigma M_y)/R$. The signs in these ratios may be disregarded; a_x and a_y have such positions that the moments of R with respect to the x and y axes have the same signs as those of ΣM_x and ΣM_y, respectively. If $\Sigma F = 0$, the resultant in general is a couple which can be determined by finding the resultant of all the forces but one; this resultant and the omitted force constitute the resultant couple. If $\Sigma M_x = \Sigma M_y = 0$ also, the resultant vanishes.

Composition of Noncoplanar Nonparallel Nonconcurrent Forces

Graphic Methods are not advantageous in general for use in determining resultants of noncoplanar nonconcurrent force systems. Therefore only the algebraic method will be discussed.

Algebraic Method. In general, the resultant is not a single force, but in such cases the system can be reduced to a force R acting through any point of the body selected and a couple C, noncoplanar with it; and if desired, R and C can in general be compounded into two noncoplanar forces. To determine R and C: select a set of coordinate axes (x, y, and z) in the body, the origin O being at the selected point referred to; determine the algebraic sums of the x, y, and z components of the given forces (ΣF_x, ΣF_y, and ΣF_z) and the algebraic sums of the moments of the forces with respect to the x, y, and z axes (ΣM_x, ΣM_y, and ΣM_z); ΣF_x, ΣF_y, and ΣF_z are the x, y, and z components of R, and ΣM_x, ΣM_y, and ΣM_z are the moments of the components of C perpendicular to the x, y, and z axes, respectively. They may be represented by vectors parallel to the axes.

$R^2 = (\Sigma F_x)^2 + (\Sigma F_y)^2 + (\Sigma F_z)^2$, and $C^2 = (\Sigma M_x)^2 + (\Sigma M_y)^2 + (\Sigma M_z)^2$; if α_1, α_2, and α_3 denote the angles between R and the x, y, and z axes, and θ_1, θ_2, and θ_3 the angles between the vector representing C and the x, y, and z axes respectively, then

$$\cos\alpha_1 = (\Sigma F_x)/R \qquad \cos\alpha_2 = (\Sigma F_y)/R \qquad \cos\alpha_3 = (\Sigma F_z)/R$$

$$\cos\theta_1 = (\Sigma M_x)/C \qquad \cos\theta_2 = (\Sigma M_y)/C \qquad \cos\theta_3 = (\Sigma M_z)/C$$

The resultant force R and the resultant couple C can be compounded into two forces as follows: take the plane of the couple so that one of the forces of the couple intersects

---

* Parallel forces are by nature *nonconcurrent*.

R; find the resultant of this force and R; this resultant and the other force of C are the two forces sought. In general the final two forces are skewed.

If the plane of C is parallel to R, C and R may be compounded into a single force by the method described in a previous paragraph headed " Composition of Single Force and Couple." If $C = 0$, the resultant is in general a single force; if $R = 0$, the resultant is in general a couple; if $C = R = 0$, the resultant vanishes.

Nature of Resultant of Nonconcurrent Forces

The Resultant of any system of *nonconcurrent forces* which are not in equilibrium is a *single force* or a *single couple* if the forces are *coplanar parallel, coplanar nonparallel,* or *noncoplanar parallel*; it is a *single force* or a *single couple* or a *noncoplanar single force and single couple* (which may be replaced by *two skewed forces*) if the forces are *noncoplanar nonparallel.**

6. PRINCIPLES OF EQUILIBRIUM

Forces in Equilibrium. A system of forces is in equilibrium if their combined action produces no change in motion of the body to which they are applied. There is no change in motion if the body remains at rest or moves in a straight line at constant speed. When a force system is in equilibrium, its resultant must be zero. This statement may be called the *general condition of equilibrium.* It implies both zero force and zero couple.

Table I. Conditions of Equilibrium

Necessary and sufficient independent conditions of equilibrium for the various force systems

	System	Algebraical		Graphical	
		No.	Conditions	No.	Conditions
Coplanar	Collinear	1	$\Sigma F = 0$	1	Force polygon closes.
	Concurrent at point O	2	$\Sigma F_x = 0$, $\Sigma F_y = 0$; or, $\Sigma F_x = 0$, $\Sigma M_a = 0$, if x direction is not perpendicular to aO; or, $\Sigma M_a = 0$, $\Sigma M_b = 0$, if aOb is not a straight line.	1	Force polygon closes.
	Parallel	2	$\Sigma F = 0$, $\Sigma M = 0$; or, $\Sigma M_a = 0$, $\Sigma M_b = 0$, if line ab is not parallel to forces.	2	Force and funicular polygons close. (Latter item means that first and last strings coincide.)
	Nonparallel nonconcurrent	3	$\Sigma F_x = 0$, $\Sigma F_y = 0$, $\Sigma M = 0$; or, $\Sigma F_x = 0$, $\Sigma M_a = 0$, $\Sigma M_b = 0$, if x direction is not perpendicular to ab; or, $\Sigma M_a = 0$, $\Sigma M_b = 0$, $\Sigma M_c = 0$, if abc is not a straight line.	2	Force and funicular polygons close. (Latter item means that first and last strings coincide.)
Noncoplanar	Concurrent at point O	3	$\Sigma F_x = 0$, $\Sigma F_y = 0$, $\Sigma F_z = 0$. Combinations of moment and resolution equations can be arranged, but are not common.	2	Force polygon closes. It is warped; hence plan and elevation must show closed. Not commonly used.
	Parallel	3	$\Sigma F_z = 0$, $\Sigma M_x = 0$, $\Sigma M_y = 0$, forces parallel to z axis. Other combinations possible but not common.		Not used.
	Nonparallel nonconcurrent	6	$\Sigma F_x = 0$, $\Sigma F_y = 0$, $\Sigma F_z = 0$, $\Sigma M_x = 0$, $\Sigma M_y = 0$, $\Sigma M_z = 0$. ΣM about every axis $= 0$, and it is often convenient to employ more than three moment equations, instead of using so many resolution equations.		The projection of the system on any plane is in equilibrium, and algebraical or graphical conditions can be used to solve such projected systems.

An oblique system of x, y, z axes may be used for reference provided no two axes are at an angle of 180° with each other. Rectangular axes are preferable generally.

---

* It is evident that *any force system whatever,* whether *concurrent or nonconcurrent,* even though it includes "sub-systems" coming under all of the various classifications discussed, can be composed into a resultant which is a *single force* or a *single couple* or a *noncoplanar single force and single couple* (or *two skewed forces*).

Body in Equilibrium. A rigid body is in equilibrium if it remains at rest or moves in a straight line at constant speed; i.e., if its state of motion does not change. This condition obtains if all the external forces acting upon it (including those due to pull of gravity, friction, etc.) form a system in equilibrium.

Conditions of Equilibrium

In a problem in *statics* a body is known to be in equilibrium; hence the system composed of all the external forces acting upon it must be in equilibrium. In such a case, tests are not needed to ascertain if equilibrium exists, but they are used to set up relations involving unknown forces, distances, or angles, and the unknown elements are then computed provided their number does not exceed the number of independent equations which may be set up by means of the equilibrium conditions. When the number of unknown elements exceeds the number of independent equations, the problem is said to be statically indeterminate.

Special Conditions. If three forces are in equilibrium they must be coplanar. and concurrent or parallel; if concurrent, each force is proportional to the sine of the angle between the other two; if parallel, each force is proportional to the distance between the other two. If a force system is in equilibrium, the resultant of any part must balance the resultant of the other part. It follows that if four coplanar nonconcurrent nonparallel forces are in equilibrium, the resultant of any two is concurrent with the other two.

Stability of Equilibrium. When a body (or collection of bodies) is in equilibrium and the state is such that if when displaced slightly in any way the body returns of itself to its original position, the equilibrium is *stable*; if when displaced slightly the body moves further from its original position, the equilibrium is *unstable*; and if when displaced slightly it remains in that displaced position, the equilibrium is *neutral* or *indifferent*. The body or collection is also said to be stable, unstable, or neutral (or indifferent) under these respective conditions. When the body is stable or unstable, the system of forces is changed by the slight displacement and is no longer in equilibrium; hence the further displacement. Only when the stability is neutral is the equilibrium of the force system undisturbed by a slight displacement of the body.

7. EQUILIBRIUM PROBLEMS

General Principles

(*a*) It frequently happens that the external force system acting on a body as a whole cannot be solved directly owing to the presence of more unknown elements (forces, distances, and angles) than there are conditions of equilibrium. In such cases, endeavor to separate the original body into simpler parts which will permit solutions. making use of the unknowns thus determined in solving the force systems acting on other sections until the complete solution, if obtainable, has been found.

(*b*) To facilitate computations, it is desirable if resolution equations are used, to resolve perpendicular to one of the unknown forces; if a moment origin is used, to select it on the action line of an unknown force; if moment axes are used, to select them so as to intersect some of the unknown forces.

(*c*) Assume senses for unknown forces. A plus answer then indicates the sense to have been correctly assumed; a minus answer, incorrect assumption.

(*d*) When force polygons are used, letter action lines of wholly known forces first and those of the remainder last. Draw the force polygon to the end of the last known vector. Vectors required to close it (remembering that the senses must read confluently from the starting point back to the same point) determine unknown magnitudes and senses and/or lines of action.

Typical Problems

I. System of Coplanar Concurrent Forces in Equilibrium *with all forces known except two whose action lines only are known.* The magnitudes and senses of these two forces are to be determined.*

Example. Two smooth cylinders rest upon a 30° plane and against a vertical wall as shown in Fig. 16. Determine all forces acting on each cylinder. (*a*) The forces involved are 100 lb, 200 lb, P, Q, R, and S, the last four being normal to the surfaces of contact (smooth surfaces). (*b*) Consider the two cylinders as a single free body. The external force system is 100 lb, 200 lb, P, R, and S (Q_1 and Q_2 are internal). The system is nonconcurrent, so does not come under typical problem I. Consider the large cylinder as a free body. The external force system is 100 lb, Q, R, and S. While

---

* This is a common problem in the determination of the stresses of a roof or bridge truss.

this system is concurrent, it cannot be solved because there are more than two unknown quantities. Next consider the small cylinder as a free body. The force system is 200 lb, P, and Q, and this is typical problem I.

Algebraic Solution. Choose X and Y directions parallel and perpendicular to the plane. $\Sigma F_x = 0 = Q_1 \frac{\sqrt{60}}{8} - 200 \sin 30°$. Hence $Q_1 = \frac{800}{\sqrt{60}} = 103.3$ lb. $\Sigma F_y = 0 = P - 200 \cos 30° - 103.3 \times 2/8$. Hence $P = 199$ lb. Consider the large cylinder as a free body. $Q_1 = Q_2 = 103.3$ lb. Use the same X and Y directions. $\Sigma F_x = 0 = S \cos 30° - 103.3 \times \frac{\sqrt{60}}{8} - 100 \sin 30°$. Hence, $S = 173.2$ lb. $\Sigma F_y = 0 = R - 100 \cos 30° - 173.2 \sin 30° + 103.3 \times 2/8$. Hence $R = 147.4$ lb.

Graphic Solution. Discussions (*a*) and (*b*) are same as above. The free body is the small cylinder. The force system is ***ab***, ***bc***, and ***ca***, and the polygon is the triangle ABC (Fig. 16). $BC = 199$ lb, $CA = 103.3$ lb. Next, consider the large cylinder as a free body. The force system is ***ac***, ***cd***, ***de***, and ***ea***. Plot the known forces AC and CD. From D draw DE parallel to *de*, and from A, AE parallel to ***ae***; these lines intersect at E. $DE = 147.4$ lb, and $EA = 173.2$ lb are the magnitudes and senses of the two unknowns.

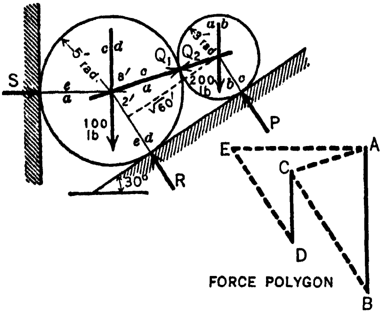

FIG. 16

If the system is concurrent and all the forces are known except one, the two unknown elements will be one angle and one magnitude and sense. Both may be determined by writing the equilibrium equations, or by drawing the force polygon.

II. System of Coplanar Parallel Forces in Equilibrium *with all forces known except two whose action lines only are known.* The magnitudes and senses of these two forces are to be determined.

Example. A beam is loaded as shown in Fig. 17 and supported at the points P and Q. Determine the reactions of the supports. Consider the beam as a free body. The external force system consists of the forces 1000 lb, 5000 lb, 2400 lb, P, and Q. This is a coplanar parallel system and is typical problem II.

Algebraic Solution. Assume senses for the reactions.

$$\Sigma M_p = 0 = -4 \times 1000 - 10 \times 5000 - 14 \times 2400 + 16Q$$

Hence $Q = 5475$ lb; correct sense was assumed.

$$\Sigma M_Q = 0 = 2 \times 2400 + 6 \times 5000 + 12 \times 1000 - 16P$$

Hence $P = 2925$ lb; correct sense assumed. As a check, apply a third equilibrium condition, $\Sigma F = 0$.

$$\Sigma F = 0 = -2925 + 1000 + 5000 + 2400 - 5475$$

Graphic Solution of the same problem involves the construction of a closed force polygon and a closed funicular polygon. On a line of indefinite length parallel to the forces, often called the *load line*, construct the force polygon by drawing vectors AB, BC, CD to represent 1000 lb, 5000 lb, 2400 lb. Let DE represent Q and EA represent P. The problem is to locate point E. This is done with the aid of the funicular polygon. Draw the rays OA, OB, OC, and OD. Construct the funicular polygon by drawing first the string between the last-lettered unknown force P (i.e, EA) and the first known force AB, and continuing it to the intersection of the last known string with the first-lettered unknown force. The closing line is ***oe***. Draw the ray OE parallel to *oe*. The unknown reactions are DE and EA.

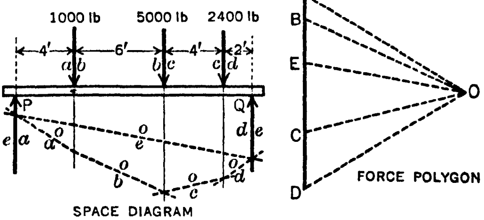

FIG. 17

For problems of this type, the algebraic solution is preferable to the graphic.

(**NOTE**: This principle cannot be applied to beams having more than two points of support. Such problems require special treatment.)

III. System of Coplanar Nonparallel Nonconcurrent Forces in Equilibrium ***with all forces known except two, of which the action line of one and a point in the action line of the***

other are known*. The magnitude and sense of the one and the magnitude, sense, and angular direction of the other are to be determined.

Example. A roof truss is loaded as in Fig. 18. The left end of the truss rests on a smooth horizontal support. The right end is secured to a wall by means of a pin. Determine the reactions. The external forces acting on the truss are the given loads, the left reaction P (vertical, on account of the smooth support), and the right reaction Q (inclined, through point M). The unknown quantities are the reactions P and Q. This is typical problem III.

Algebraic Solution. Assume P upward.

$\Sigma M_M = 0 = 20{,}000 \times 18 + 25{,}000 \times 24 \cos 30° - 36P$; hence, $P = 24{,}430$ lb; correct sense assumed.

Assume Q upward to the left at angle θ with horizontal.

$\Sigma F_x = 0 = 25{,}000 \sin 30° - Q \cos \theta$; $\Sigma F_y = 0 = -25{,}000 \cos 30° - 20{,}000 + 24{,}430 + Q \sin \theta$.

Solving simultaneously, $Q = 21{,}300$ lb, and $\theta = 54°$. Sense and direction were correctly assumed, hence Q acts upward to the left at 54° to the horizontal. As a check, apply condition $\Sigma M_P = 0$. $\Sigma M_P = 0 = -25{,}000 \times 12 \cos 30° - 20{,}000 \times 18 + 21{,}300 \times 36 \sin 54°$.

Graphic Solution. ab and bc are the action lines of the given loads, cd of the reaction P and da of the reaction Q. Draw the vectors AB and BC, and a line through C, parallel to cd. Choose a pole and draw the rays. Construct the funicular polygon, drawing oa through M, and draw closing string od from K to M. Draw OD through O parallel to od to intersect CD at D. Draw DA. Vectors CD and DA represent the two unknown forces, $P = 24{,}430$ lb and $Q = 21{,}300$ lb. The action line of Q is da, making angle with horizontal = 54°.

Special Case. A case coming under the above classification which requires a variation in treatment when employing the graphic method is one in which the action lines of all three forces are known but their magnitudes and senses are unknown. The procedure is in general similar to methods employed before except that, in the graphic solution, two of the unknown forces which are concurrent must be replaced by their unknown resultant acting through their point of concurrency along an unknown action line. After the magnitude and sense of this resultant have been determined (by the method employed in the above example), it is resolved into its two components along the action lines of the two unknown forces which it had replaced. These components represent the magnitudes and senses of this pair of forces.

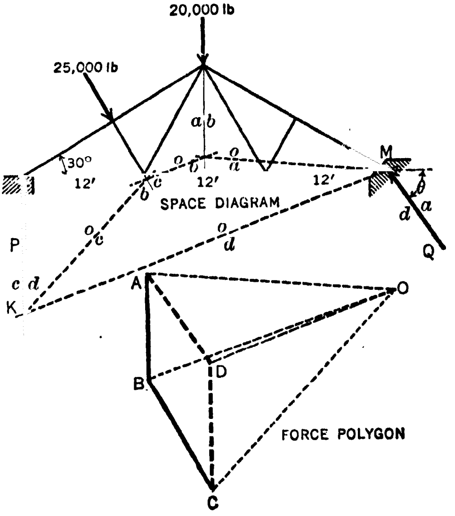

Fig. 18

IV. System of Noncoplanar Nonparallel Nonconcurrent Forces in Equilibrium *with one force completely known and action lines (or a point in the action line) of the others known.* All unknown force magnitudes, action lines and senses are to be determined.

Example. The crane (Fig. 19) is supported by a socket at the foot of the post at D; is kept from overturning by the backstays AB and AC; and carries a load of 600 lb (E, A, F, G, D, are in the vertical XY plane). Determine the axial components of the reaction on the post at D and the tensions in the backstays. The external forces acting on the post are the load, the reaction at D, and the tensions in the backstays at A. This is typical problem IV. Moment equations are the most convenient to apply for this solution.

$$\Sigma M_{BC} = 0 = 600 \times 40 - 20\,D_y; \quad D_y = 1200 \text{ lb}$$

$$\Sigma M_{ZA} = 0 = 600 \times 20 - 16\,D_x; \quad D_x = 750 \text{ lb}$$

$$\Sigma M_{XA} = 0 = 600 \times 4 - 16\,D_z; \quad D_z = 150 \text{ lb}$$

$$\Sigma M_{XC} = 0 = AB \times \frac{16}{\sqrt{881}} \times 25 - 1200 \times 10 + 600 \times 6; \quad AB = 622 \text{ lb}$$

$$\Sigma M_{XB} = 0 = AC \times \frac{16}{\sqrt{756}} \times 25 + 600 \times 19 - 1200 \times 15; \quad AC = 452 \text{ lb}$$

---

* This is a common problem in the determination of the reactions on a roof truss sustaining wind pressures, the truss being fixed at one end and resting on rollers at the other.

The senses of all forces are as shown in Fig. 19.

The magnitude, action line, and sense of the resultant force on the post at *D* can be readily determined (if desired) by the Parallelepipedon Law.

Truss Analysis

A Truss is a framework * for carrying loads, each *member* of which is subjected only to tension or compression loads. The members are usually pin-jointed with loads applied only at the joints.

The Stress in a Member at any section is the force which either of its two parts exerts internally on the other part as a result of the external forces acting on the member. Longitudinal stresses, like external longitudinal forces, may be either tensile or compressive.

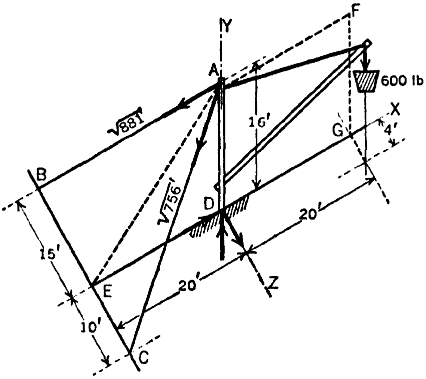

FIG. 19

The Analysis of a Truss under a given loading condition refers to the determination of the stresses in its members due to the loads.

Analysis by Method of Sections. First, determine the reactions on the truss due to the loads; second, imagine the truss separated into two distinct parts (that is, pass a section through the truss) so that the member under consideration is one of the members cut and so that the system of forces, including stresses, acting on either part of the truss is solvable for the desired stress; third, solve the system.

To Pass the Section, suppose the stress in *HI* (Fig. 20*a*) is required, the truss being supported at its ends and bearing five loads *L* and one *P*, and suppose the reactions determined. Trying section 1–1, the force system on the left part of the truss (Fig. 20*b*) is a nonconcurrent one of seven forces, and includes four unknown stresses, S_1, S_2, S_3, and S_4; it is not solvable for the desired stress S_1. Trying section 2–2, the force system on the lower part (Fig. 20*c*) is a concurrent one, and includes four unknown stresses, S_1, S_2, S_5, and S_6; it is not solvable. Trying section 3–3, the force system on the left part (Fig. 20*d*) is nonconcurrent with three unknown stresses, S_1, S_7, and S_8; it is solvable. In some instances different sections may be used, each leading to a solution.

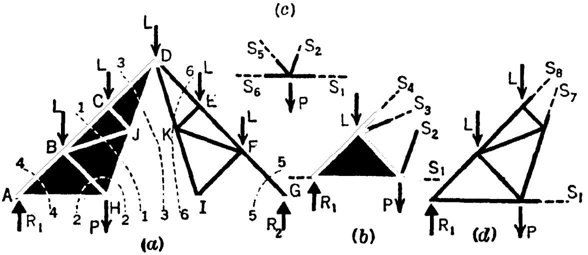

FIG. 20

S_1 having been determined, the force system of Fig. 20*b* becomes solvable, and then, with S_2 also determined, the force system of Fig. 20*c* may be solved.

Algebraic Solution. Following the general method of procedure outlined above, determine the various stresses by employing algebraic conditions of equilibrium in manners similar to those illustrated heretofore under " Equilibrium Problems."

Graphic Solution. Following the general method of procedure outlined above, determine the various stresses by employing graphic conditions of equilibrium.

In Making the Imaginary Separations of the Truss, care should be taken to cut not more than three members in which the stresses are unknown. It is advantageous to make

---

* *Redundant frames* (i.e., ones having more members than necessary to preserve their shapes under the loading conditions) are not considered in this section, since the stresses in them cannot be determined by elementary static methods.

the separation so that not more than two such members are cut. If this is done, a single force polygon will determine the two unknowns, whereas if three are cut, a force polygon and an equilibrium polygon, or the equivalent, are necessary for determining the three unknowns.

Analysis by Method of Joint Resolution.* Consider the pin at each joint as a body acted upon by forces in equilibrium.

Algebraic Solution. Determine the various stresses by employing algebraic conditions of equilibrium in manners similar to those illustrated heretofore under "Equilibrium Problems."

Graphic Solution. For each joint, draw the force polygon. In doing so, it will be advantageous to represent the forces in the order in which they occur about the joint. A force polygon so drawn will be called a polygon for the joint; and for brevity, if the order taken is clockwise, the polygon will be called a clockwise polygon, and if counterclockwise, it will be called a counterclockwise polygon. If the polygons for all the joints of a truss are drawn separately, the stress in each member will have been represented twice. It is possible to combine the polygons so that it will not be necessary to represent the stress in any member more than once, thus reducing the number of lines to be drawn. Such a combination of force polygons is called a *stress diagram.* Each triangular space in the truss diagram is marked by a small letter; also the space between consecutive action lines of the loads and reactions. Then the two letters on opposite sides of any line serve to designate that line, and the same large letters are used to designate the magnitude of the corresponding force.

To construct a stress diagram for a truss under given loads:

(1) Determine the reactions. (2) Letter the truss diagram as directed. (3) Construct a force polygon for all the external forces applied to the truss (loads and reactions), representing them in the order in which their application points occur about the truss, clockwise or counterclockwise. (4) On the sides of that polygon construct the polygons for all the joints. They must be clockwise or counterclockwise according as the polygon for the loads and reactions was drawn clockwise or counterclockwise. (The first polygon drawn must be for a joint at which only two members are fastened; the joints at the supports are usually such. Next, that joint is considered, and its polygon is drawn, at which not more than two stresses are unknown.)

Example. Fig. 21 represents a roof truss sustaining loads of 600, 1000, 1200, and 1800 lb; the right reaction is 2100 lb, and the left 2500 lb. *ABCDEFA* is a polygon for the loads and reactions, these being represented in the order in which their points of application occur about the truss. The polygon for joint 1 is *FABGF*; the force *BG* acts toward the joint, hence *bg* is under compression, and *GF* acts away from the joint, hence *gf* is in tension. The polygon for joint 2 is *CDEHC*; the force *EH* acts away from the joint, hence *eh* is in tension; and *HC* acts toward the joint, hence *hc* is in compression. The polygon for joint 3 is *HEFGH*; the force *GH* acts away from the joint and hence *gh* is in tension. If the work has been done correctly, *GH* is parallel to *gh*. (In Fig. 21*a* all the polygons are clockwise, and in Fig. 21*b*, counterclockwise.)

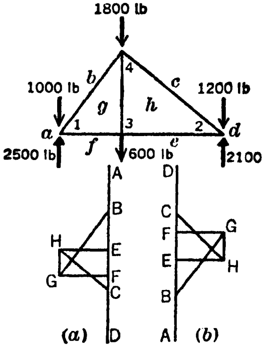

FIG. 21

8. CENTER OF GRAVITY

Definitions

The Centroid of a system of parallel forces having fixed application points is the point through which their resultant will always pass regardless of how the forces may be turned, provided they remain parallel.

The Center of Gravity of a Body † *or system of bodies* is the *centroid of the forces of gravitation* ‡ acting upon all the particles thereof. Referring the application points of such a force system to a set of coordinate axes, the coordinates of the centroid, or center of gravity (c.g.), are:

$$\bar{x} = (\Sigma F_i \cdot x_i)/\Sigma F_i = \frac{\int xdF}{F}; \quad \bar{y} = (\Sigma F_i \cdot y_i)\ /\Sigma F_i = \frac{\int ydF}{F}; \quad \bar{z} = (\Sigma F_i \cdot z_i)\ /\Sigma F_i = \frac{\int zdF}{F}$$

---

* This method is not usually so convenient for determining algebraically the stress in a single specified member.

† Sometimes called *center of mass* or *center of inertia.*

‡ For practical purposes, the forces of gravitation may be considered as parallel.

in which F_i represents the force on (or weight of) one particle and x_i, y_i, z_i are the coordinates of its application point. If a group of bodies is involved, the coordinates of the center of gravity of the group are:

$$\bar{x} = (\Sigma W_i \cdot \bar{x}_i)/\Sigma W_i; \quad \bar{y} = (\Sigma W_i \cdot \bar{y}_i)/\Sigma W_i; \quad \bar{z} = (\Sigma W_i \cdot \bar{z}_i)/\Sigma W_i$$

in which W_i represents the weight of one body and $\bar{x}_i$, $\bar{y}_i$, $\bar{z}_i$ are the coordinates of its center of gravity.* A body (or system of bodies), if supported at its center of gravity, will remain at rest in any position.

The Center of Gravity of Part of a Body may be located by the rule that its moment, with respect to any plane, equals the moment of the whole minus, algebraically, the moment of the remainder.

The Center of Gravity of a Line, Surface, or Volume is that point which would be the center of gravity if the line were replaced by a homogeneous rod of infinitesimal diameter, the surface by a homogeneous plate of infinitesimal thickness, or the volume by a homogeneous body.

Symmetry. Two points are symmetrical with respect to a third point if the line joining the two is bisected by the third. Two points are symmetrical with respect to a line or a plane if the line joining them is perpendicular to the given line or plane and is bisected by it. A body, line, surface, or volume is symmetrical with respect to a point, a line, or a plane if all the points of the body, line, surface, or volume can be paired so that each pair is symmetrical with respect to the point, line, or plane. If a homogeneous body, or a line, surface, or volume is symmetrical with respect to a point, line, or plane, its center of gravity is at the point, in the line or in the plane.

The Static Moment of a body (having weight), a line (having length), a surface (having area), or a solid † (having volume) with respect to any plane is the product of the weight, length, area, or volume and the distance of the center of gravity of the body, line, surface, or solid from the plane. The static moment of a plane line or plane surface with respect to a straight line in the plane is the product of the length or area and the distance of the center of gravity of the line or surface from the reference line. A static moment is regarded as positive or negative according as the corresponding center of gravity is on the positive or negative side of the reference plane or line.

Determination of Center of Gravity Location

When practicable, determination of center of gravity location by algebraic or integration methods, based on dividing the sum of the moments by the sum of the forces, is generally the simplest process. For some bodies of non-homogeneous nature or of very irregular shape, one of the following methods of procedure may be necessary or at least preferable:

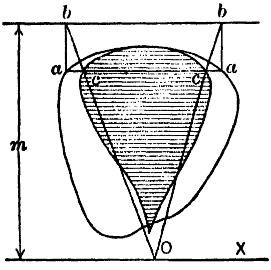

FIG. 22

Graphic Method. For application to *plane* figures.‡ Referring to Fig. 22, take a point O and a line bb on opposite sides of the figure at any convenient distance m apart; project any width of the figure parallel to bb as aa on bb, connect the projections bb with O and note the intersections cc; determine other points cc and draw a smooth curve through them as shown; measure the area A' within the curve cc; then $A'm$ is the static moment of the given figure with respect to OX; if A is the area of the given figure and y the distance of its center of gravity from OX, $y = A'm/A$. In a similar way the distance of the center of gravity from a line perpendicular to OX can be determined and its exact position thus definitely located.

Suspension Method. For application to *plane* figures.§ Suspend the body (or a model representing it) from a point near its edge and mark on it the direction of a plumb-line hung from that point. Repeat this operation, using a second suspension point. The center of gravity is at (or behind) the intersection of the two markings.

Weighing Method. Generally applied where location of c.g. in one plane only is required. Determine weight W of the body and then support it on a knife-edge (Fig. 23) and on a point support resting upon a platform scale. Weigh reaction R of the point support and measure horizontal distance a between the point and the knife-edge. Then the horizontal distance from the knife-edge to the center of gravity is $\bar{x} = Ra/W$.

---

* As F (in the gravitational system of units) equals W, these symbols may be used interchangeably in the two sets of formulas. Also, any one of the expressions may be read as "the sum of the moments divided by the sum of the forces (or weights)."

† The word "solid" where used herein denotes "that which has volume." Care should be taken to distinguish this from a "body," which has "mass" (as well as "volume"). Some writers use the word "solid" to denote at various times either volume or mass, which is sometimes confusing. In this section, the word "volume" is frequently used even in preference to "solid" to avoid the possibility of confusion with "mass."

‡ Including areas or flat homogeneous bodies of uniform thickness.

§ Including areas or flat bodies of uniform homogeneous thickness.

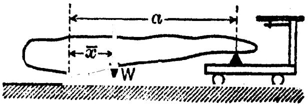

FIG. 23

Balancing Method. For general application. Balance the body (or a model representing it) on a straight-edge, marking on the body the vertical plane containing the edge. Repeat for two more balancing positions of the body. The center of gravity is at the point common to the three planes thus determined.

9. MOMENT OF INERTIA

Plane Surfaces—Definitions

The Moment of Inertia of a Plane Surface (or figure) **with respect to** (or about) **a line** (or axis) is the sum of the products obtained by multiplying the area of each element of the surface by the square of its distance from the line.* Letting I_x denote moment of inertia about an X axis:

$$I_x = \int y^2 dA$$

in which A is the total area and y is the perpendicular distance of any element of area dA from the axis. The moment of inertia of a surface is obviously the sum of the moments of inertia of its parts. The moment of inertia of a plane surface is **rectangular** if the axis used is *in* the plane of the area; it is **polar** if the axis is *perpendicular* to the plane of the area.

The Radius of Gyration of a Plane Surface with respect to a line is the length whose square multiplied by the area of the surface equals the moment of inertia of the surface with respect to the line. Letting k denote radius of gyration:

$$I = k^2 A \quad \text{or} \quad k = \sqrt{I/A}$$

in which I is the moment of inertia and A the area.

The Product of Inertia of a Plane Surface with respect to a pair of coordinate axes in the plane is the algebraic sum of the products obtained by multiplying the area of each element of the surface by its coordinates.* Letting U_{xy} denote product of inertia with respect to X and Y axes:

$$U_{xy} = \int xy dA$$

in which A is the total area and x and y are the coordinates of any element of area dA.

The Principal Axes of Inertia of a Plane Surface at a Particular Point in the plane are the two axes about which the moments of inertia are greater and less than for any other axis, through the point in the plane.† The corresponding moments of inertia are called the **principal moments of inertia** of the surface at the point. The principal axes are always at right angles to each other. The product of inertia with respect to them is zero.

The Customary Engineer's Unit for both moment and product of inertia of a surface is biquadratic inches (in.^{4}).

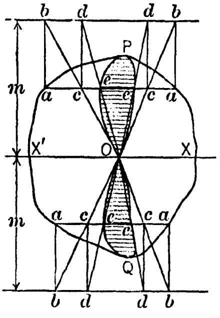

FIG. 24

Determination of Moment of Inertia of Plane Surfaces

When practicable, determination of moment of inertia with respect to an axis by algebraic or integration methods is generally the simplest process. For some surfaces of very irregular shape, the following graphic method of procedure may be necessary or at least preferable:

Graphic Method. Let *aaaa* (Fig. 24) be the outline and XX' the axis with respect to which the moment of inertia is desired; at any convenient distance m from XX' draw two parallels (but if XX' does not cut the figure, only one parallel, the one on the opposite side of the figure from XX'); draw any line as *aa* parallel to XX' and project the points *aa* on the nearer parallel; join the projections *bb* to any point O in XX', and note the intersections *cc* on *aa*; project *cc* on the same parallel; join the projections *dd* with O, and note the

---

* Moment of inertia is always positive and never zero. Product of inertia may be positive, zero, or negative, depending upon the distribution of the area with respect to the axes. If a surface has an axis of symmetry, its product of inertia with respect to that axis and one perpendicular thereto is zero.

† In certain special cases, as for axes through the point in the center of a circular area, the moment of inertia is the same for any axis and therefore there is no principal axis through that point.

intersections *ee* on *aa*. In a similar manner determine points like *ee* for other widths like *aa*, and connect all points *e* as shown. Then measure the area of the loops *OPO* and *OQO*; denoting this combined area by A'', $I = A''m^2$. (There will be only one loop if only one parallel *bb* is used.)

Transformation Formulas—Plane Surfaces

Parallel Axes Theorems. Let I = *moment of inertia* (either rectangular or polar) of a plane figure with respect to any line or axis, $\bar{I}$ = that with respect to a parallel axis passing through the center of gravity of the figure, d = distance between the axes, k and $\bar{k}$ = the radii of gyration with respect to the same axes respectively, and A = area of the figure; then

$$I = \bar{I} + Ad^2 \quad \text{and} \quad k^2 = \bar{k}^2 + d^2$$

These show that with respect to all parallel axes the moment of inertia and the radius of gyration are least for the one passing through the center of gravity of the figure.

Similarly, let U = *product of inertia* of a plane figure with respect to a pair of coordinate axes in the plane, and $\bar{U}$ = that with respect to a parallel pair whose origin is at the center of gravity; $\bar{x}$, $\bar{y}$ the coordinates of the center of gravity referred to the first pair, and A the area of the figure; then $U = \bar{U} + A\bar{x}\bar{y}$.

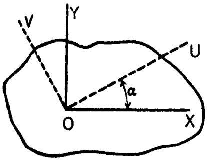

Fig. 25

Relation of Rectangular and Polar Moments of Inertia. Let I_x, I_y, and J_z = the moments of inertia of a plane figure with respect to x, y, and z axes respectively, the axes being *at right angles* to each other and the x and y axes in the plane; and let k_x, k_y, and k_z = the corresponding radii of gyration; then $J_z = I_x + I_y$, $k_z^2 = k_x^2 + k_y^2$.

Rotated Axes Theorem. Let XOY and UOV (Fig. 25) be two sets of rectangular coordinate axes with a common origin and in a given plane figure. I_x, I_y, I_u, I_v = moments of inertia of the figure with respect to x, y, u, and v axes respectively; U_{xy} and U_{uv} = its products of inertia with respect to the sets of axes respectively; α = angle through which x axis must be rotated to bring it into u axis, regarded as positive or negative according as the turning is counterclockwise or clockwise. Then $I_u + I_v = I_x + I_y$, and

$$I_u = I_x \cos^2 \alpha + I_y \sin^2 \alpha - U_{xy} \sin 2\alpha$$
$$U_{uv} = {}^1\!/_2(I_x - I_y) \sin 2\alpha + U_{xy} \cos 2\alpha$$

If OU and OV are *principal axes* (see definition above), $U_{uv} = 0$ and therefore $\tan 2\alpha = 2U_{xy}/(I_y - I_x)$. Hence, the principal axes of a figure at a point can be readily found if the moments of inertia and the product of inertia of the figure with respect to two rectangular axes through the point and in the plane are known.* The *principal moments of inertia* are then I_u from the formula above and I_v from the same formula after replacing α by $\left(\alpha + \frac{\pi}{2}\right)$. As a check, $I_u + I_v = I_x + I_y$.

Graphic Transformations—Plane Surfaces

The Inertia Circle is a device for determining *graphically* the moment of inertia of a plane figure with respect to any line of the plane through a given point; and the principal axes and principal moments of inertia for the same point. To construct the circle, it is necessary to know the moments of inertia and the product of inertia with respect to two rectangular axes through the point, in the plane figure. Suppose I_x, I_y, and U_{xy} given for the shaded area in Fig. 26. To convenient scale, plot OX' and OY' to represent I_x and I_y, and $Y'A$ to represent U_{xy} (downward if negative and upward if positive). Center C is midway between X' and Y'. With CA as radius, describe the inertia circle. To find I_u, draw chord AB parallel to axis OU; draw perpendicular BU'. OU' (to scale) = I_u, and BU' (to scale) = U_{uv}. OM, parallel to $A2$, is axis of least I; and a parallel to $A1$, through O, is axis of greatest I. $O2$ (to scale) is the value of least $I = I_2$; and $O1$, value of greatest $I = I_1$. *Least radius of gyration* for an axis through point $O = \sqrt{I_2/\text{area}}$.

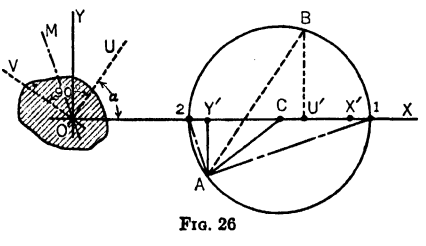

Fig. 26

---

[*] If U_{xy} and $(I_y - I_x)$ are both zero, there is no principal axis through the point.

Bodies—Definitions

The Moment of Inertia of a Body with respect to (or about) a line (or axis) is the sum of the products obtained by multiplying the mass of each elementary part by the square of its distance from the line.† Letting I_x denote moment of inertia about an X axis:

$$I_x = \int y^2\, dm$$

in which m is the total mass and y is the perpendicular distance of any element of mass dm from the axis.* The moment of inertia of a body is obviously the sum of the moments of inertia of its parts.

The Center of Gyration of a Body with respect to a line is a point at such a distance from the line that, if the entire mass of the body were concentrated there, its moment of inertia would be the same as that of the body.

The Radius of Gyration of a Body with respect to a line is the distance from the center of gyration to the line. Letting k denote radius of gyration:

$$I = k^2\, m \quad \text{or} \quad k = \sqrt{I/m}$$

in which I is the moment of inertia and m the mass.

The Product of Inertia of a Body with respect to a pair of coordinate planes is the algebraic sum of the products obtained by multiplying the mass of each element of the body by its coordinates with reference to those planes.† Thus with respect to YOZ and ZOX (Fig. 27), ZOX and XOY, and XOY and YOZ planes, the products of inertia are respectively:

$$U_{xy} = \int xydm; \quad U_{yz} = \int yzdm; \quad U_{zx} = \int zxdm$$

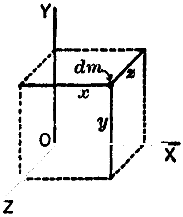

FIG. 27

The Principal Axes of Inertia of a Body at a Particular Point. The values of moments of inertia of a body for all axes through a given point are in general unequal; for one axis the moment of inertia is greater and for another it is less than for any other axis through the point. These two axes are at right angles, and they together with one at right angles to their plane and passing through the point are **principal axes of inertia of the body at the point**; the corresponding moments of inertia are the **principal moments of inertia of the body at the point.** If the point is the center of gravity of the body, the axes and moments are called *central principal axes* and *central principal moments of inertia.* For a set of principal axes, the three products of inertia, with respect to the **principal planes** determined by them, are zero.

The Customary Engineer's Unit for both moment and product of inertia is slug-ft.^{2}

Transformation Formulas—Bodies

Parallel Axes Theorems. Let I = moment of inertia of a body with respect to any line or axis, $\bar{I}$ = that with respect to a parallel axis passing through the center of gravity of the body, d = distance between the axes, k and $\bar{k}$ = the radii of gyration with respect to the same axes respectively, and m = mass of the body; then

$$I = \bar{I} + md^2 \quad \text{and} \quad k^2 = \bar{k}^2 + d^2$$

Rotated Axes Theorems. Let I_x, I_y, and I_z denote the moments of inertia of a body with respect to rectangular axes x, y, and z respectively; U_{xy}, U_{yz}, and U_{zx} its products of inertia with respect to yz and zx planes, zx and xy planes, and xy and yz planes respectively; I the moment of inertia of the body with respect to a line through the origin of coordinates having direction-angles α, β, and γ; then

$$I = I_x \cos^2\alpha + I_y \cos^2\beta + I_z \cos^2\gamma - 2U_{yz}\cos\beta\cos\gamma - 2U_{zx}\cos\gamma\cos\alpha - 2U_{xy}\cos\alpha\cos\beta$$

If $U_{xy} = U_{yz} = 0$, the y axis is a principal axis at the origin.
If $U_{yz} = U_{zx} = 0$, the z axis is a principal axis at the origin.
If $U_{zx} = U_{xy} = 0$, the x axis is a principal axis at the origin.

If a homogeneous body has a plane of symmetry, any perpendicular to the plane is a principal axis of the body at the point where the line pierces the plane. If it has two planes of symmetry at right angles to each other, their intersection is a principal axis at any point of the intersection, the other two being in the planes of symmetry. If it has three planes of symmetry, their lines of intersection are the central principal axes of the body.

---

* Strictly speaking, this is the moment of inertia of the *mass* of a body. If m be replaced by w = weight, the result is the moment of inertia of the *weight* of a body.

† Moment of inertia is always positive and never zero. Product of inertia may be positive, zero, or negative, depending upon the distribution of the mass with respect to the coordinate planes. If a body has a plane of symmetry, its product of inertia with respect to that plane and one perpendicular thereto is zero.

Properties of Various Lines, Surfaces, Volumes, and Bodies

Symbols: I_i = Rectangular Moment of Inertia; k_i = Corresponding Radius of Gyration; J_O = Polar Moment of Inertia about axis through O perpendicular to plane; k_O = Corresponding Radius of Gyration; m = mass = W/g where W = weight and g = acceleration due to gravity. Moments of Inertia of bodies are given in terms of mass. For their values in terms of weight, replace m by W in the formulas.

35. Torus 	C.G. is at O = geometrical center. $I_g = \frac{m(4R^2 + 5r^2)}{8}$; $I_c = \frac{m(4R^2 + 3r^2)}{4}$ $k_g = \sqrt{\frac{4R^2 + 5r^2}{8}}$; $k_c = \frac{\sqrt{4R^2 + 3r^2}}{2}$
36. Ellipsoid 	C.G. is at O = geometrical center. C.G. of *one octant* is at point having coordinates: $\bar{x} = \frac{3a}{8}$; $\bar{y} = \frac{3b}{8}$; $\bar{z} = \frac{3c}{8}$ *For Complete Ellipsoid*: $I_x = \frac{m}{5}(b^2 + c^2)$; $I_y = \frac{m}{5}(a^2 + c^2)$; $I_z = \frac{m}{5}(a^2 + b^2)$ $k_x = \sqrt{\frac{b^2 + c^2}{5}}$; $k_y = \sqrt{\frac{a^2 + c^2}{5}}$; $k_z = \sqrt{\frac{a^2 + b^2}{5}}$
37. Paraboloid 	C.G. is on axis of symmetry at O. Distance from base $= \frac{h}{3}$. $I_g = \frac{mr^2}{3}$; $I_c = \frac{m}{18}(3r^2 + h^2)$ $k_g = \frac{r}{\sqrt{3}}$; $k_c = \sqrt{\frac{3r^2 + h^2}{18}}$

KINEMATICS

10. MOTIONS OF A PARTICLE

Motion of a Particle with respect to other particles or objects is its state of continual changing of position with respect to them.

Rectilinear Motion is motion along a straight path.

Curvilinear Motion is motion along a curved path which may be either planar or skewed.

Displacement of a Particle is its change of position and is a vector quantity. If A is the position of a particle at a time t_1, and B its position at a later time t_2, its displacement in the time interval $t_2 - t_1 = \Delta t$ is the vector AB, no matter whether the path is straight or curved.

Velocity of a Particle is its time rate of displacement (i.e., rate of change of position) and is a vector quantity. **Speed** is the magnitude of velocity without reference to direction or sense.

Acceleration of a Particle is its time rate of change of velocity and is a vector quantity.

11. RECTILINEAR MOTION

Velocity. Let s = distance measured along the path of a particle, s_1 = distance from origin at time t_1, s_2 = distance at a later time t_2, $\Delta s = s_2 - s_1$ = *displacement** in time interval $\Delta t = t_2 - t_1$. Then *average velocity* $= \Delta s/\Delta t$. If the position changes at a uniform rate (which implies no change in sense), actual velocity at any time $= \Delta s/\Delta t$. For every case, *instantaneous velocity* $= v = \dfrac{ds}{dt} = \underset{\Delta t \to 0}{\text{limit}} \left(\dfrac{\Delta s}{\Delta t}\right)$. *Unit of Velocity* is any distance unit divided by any time unit. *Units* commonly used are feet per second and miles per hour.

Acceleration. Let v_1 = velocity of particle at time t_1, v_2 = velocity at a later time t_2, $\Delta v = v_2 - v_1$ = change in velocity in time interval $\Delta t = t_2 - t_1$. Then *average acceleration* $= \Delta v/\Delta t$. If the velocity changes at a uniform rate, the actual acceleration at any time $= \Delta v/\Delta t$. For every case, *instantaneous acceleration* equals

$$a = \frac{dv}{dt} = \frac{d^2s}{dt^2} = \underset{\Delta t \to 0}{\text{limit}} \left(\frac{\Delta v}{\Delta t}\right)$$

Unit of acceleration is any velocity unit divided by any time unit. A unit commonly used is feet per second per second (i.e., ft per sec^2).

Formulas for Determination of a, v, s, t. If s is given algebraically in terms of t, then v and a may be determined in terms of t by differentiation as indicated above. If a is given algebraically in terms of t, then v and s may be determined in terms of t by integration. Other relations not involving t may be determined by similar methods. The common formulas are:

$$v = \frac{ds}{dt}; \qquad a = \frac{dv}{dt} = \frac{d^2s}{dt^2}; \qquad \frac{a}{v} = \frac{dv}{ds}$$

$$s_2 - s_1 = \int_{t_1}^{t_2} v\,dt; \quad v_2 - v_1 = \int_{t_1}^{t_2} a\,dt; \quad t_2 - t_1 = \int_{s_1}^{s_2} \frac{ds}{v} = \int_{v_1}^{v_2} \frac{dv}{a}; \quad v_2^2 - v_1^2 = 2\int_{s_1}^{s_2} a\,ds$$

For Uniform Acceleration, a = constant; $v = at + v_0$; $s = {}^1/_2 at^2 + v_0t + s_0$; $v^2 = 2a(s - s_0) + v_0^2$; v_0 being initial velocity and s_0 initial distance.

If algebraic relations between a, v, s, and t are not given but a number of pairs of corresponding values of two of the variables are known, curves may be plotted for the approximate determination of other corresponding pairs of values and of other unknowns, within the range of the data. Such curves are discussed later under "Motion Graphs."

Examples of Rectilinear Motion

Falling Body.† If a body *falls from rest* in a vacuum, $v_0 = 0$, $s_c = 0$, and $a = g = 32.2$ ft per sec^2 (approx.). Hence $v = gt = \sqrt{2gs}$; $s = {}^1/_2 gt^2$. If a body is *projected upward* at an initial velocity v_0, $a = -g$ and the formulas become $v = -gt + v_0 = \sqrt{-2gs + v_0^2}$; $s = -\frac{1}{2}gt^2 + v_0t$. Total ascent (to highest position) $= \frac{v_0^2}{2g}$, and time required $= \frac{v_0}{g}$.

---

* The difference in distances along the path equals the displacement *only* when the path is a straight line. (See definition of displacement.)

† Rotation disregarded and body considered as a particle.

Crank and Connecting-rod Mechanism. The problem is to find expressions for the velocity and acceleration of any point in the crosshead, as A in Fig. 1. Such a point describes rectilinear motion. Let $c = r/l$, n = revolutions per second (assumed constant), ω = radians of angle described by crank per second, and s = distance of A from its extreme left position, all distances expressed in feet. Then,

$$s = (l + r) - l(1 - c^2 \sin^2 \theta)^{1/2} - r \cos \theta$$

$$v = r\omega\left(\sin \theta + \frac{c \sin 2\theta}{2(1 - c^2 \sin^2 \theta)^{1/2}}\right); \quad a = r\omega^2\left(\cos \theta + \frac{c \cos 2\theta + c^3 \sin^4 \theta}{(1 - c^2 \sin^2 \theta)^{3/2}}\right)$$

The above formulas are exact; close approximations are:

$$s = r(1 - \cos \theta) + \frac{1}{4}cr(1 - \cos 2\theta); \quad v = r\omega(\sin \theta + \frac{1}{2}c \sin 2\theta)$$

$$a = r\omega^2(\cos \theta + c \cos 2\theta)$$

Motion Graphs

Space-time, velocity-time, acceleration-time, velocity-space, acceleration-space curves for a particle are graphs showing the relations between magnitudes of s and t, v and t, a and t, v and s, a and s, respectively. Figs. 2–6 illustrate such graphs but do not correspond to the same motion.

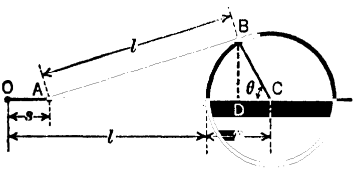

FIG. 1

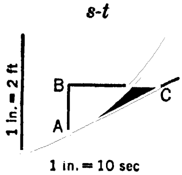

FIG. 2

Space-time Diagram. In Fig. 2, the *slope* of the curve at any point represents the magnitude of the velocity. If AB and BC are measured by the s and t scales of the drawing respectively, the slope equals the velocity magnitude; thus if $AB = 0.2$ in. and $BC = 0.4$ in., $v = 0.4/4 = 0.1$ ft per sec.

Velocity-time Diagram. In Fig. 3, the *slope* of the curve at any point represents the magnitude of the acceleration.* If AB and BC are measured by the v and t scales respectively, the slope equals the acceleration magnitude; * thus if $AB = 0.3$ in. and $BC = 0.5$ in., $a = 1.2/5 = 0.24$ ft per sec per sec. The *area* included between any two ordinates (as AE and DF), the curve, and the t axis, represents the displacement † of the moving point in the time EF. If area is below the time axis, it is considered minus. If the area is computed by multiplying its average ordinate measured by the velocity scale (this being the average velocity) by EF measured by the time scale, the product equals the displacement; thus if the average ordinate is 0.35 in., and EF is 0.4 in., the displacement $= 1.4 \times 4 = 5.6$ ft.

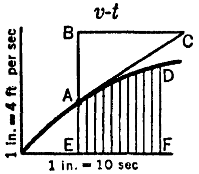

FIG. 3

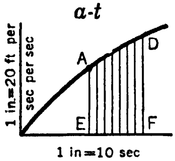

FIG. 4

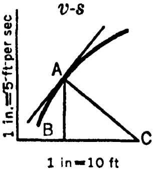

FIG. 5

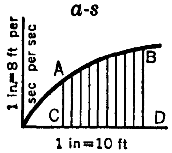

FIG. 6

Acceleration-time Diagram. In Fig. 4, the *slope* represents the rate at which the acceleration is changing.‡ The *area* (plus above and minus below time axis) included between any two ordinates (as AE and DF), the curve, and the t axis, represents the velocity change in the time EF.‡ Thus if the average ordinate is 0.3 in. and EF is 0.2 in., the velocity change $= 6 \times 2 = 12$ ft per sec.

---

* For curvilinear motion, this is tangential acceleration only.

† For curvilinear motion, this is distance along the path (not displacement).

‡ For rectilinear motion only.

Velocity-space Diagram. In Fig. 5, the subnormal represents the acceleration.* If the length of the subnormal is multiplied by the square of the velocity scale number and the product is divided by the space scale number, the result will equal the acceleration; * thus suppose that the subnormal $BC = {}^1/_3$ in., then $a = ({}^1/_3 \times 25)/10 = 0.83$ ft per sec per sec.

Acceleration-space Diagram. In Fig. 6, the area (plus above and minus below space axis) included between two ordinates (as *AC* and *BD*), the curve, and the *s* axis, represents the change in the velocity square. If the area is computed by multiplying the mean ordinate measured by the acceleration scale by *CD* measured by the space scale, the product times two equals the change in the velocity square; thus if the average ordinate = 0.3 in., and $CD = 0.4$ in., the change $= 2.4 \times 4 \times 2 = 19.2$.

Simple Harmonic Motion

Simple Harmonic Motion and Its Motion Graphs have wide application in physics and engineering. If a point *P* moves in a circular path of radius *r* at uniform speed, its projection on any diameter has *simple harmonic motion.* The radius *r* is called the *amplitude.* The *period* is the time required for the projection to go from one end of the diameter to the other and back. The *frequency* is the number of periods per unit time, which makes it the reciprocal of the period. Angle *XOP* (Fig. 7) (considered as less than 2π radians) is the *phase angle. The displacement* at any time is the distance of the point having simple harmonic motion from the center of its path or range.

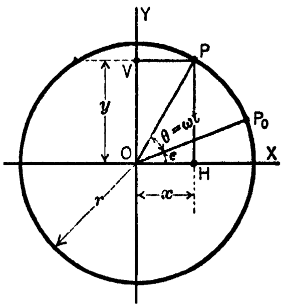

FIG. 7

When $t = 0$, let *P* be at P_0. ϵ is called the *lead angle* (*lag, if negative*). For simple harmonic motion (*SHM*) of *V* in the vertical diameter, $y = r \sin (\theta + \epsilon) = r \sin (\omega t + \epsilon)$, in which $\omega = \frac{d\theta}{dt}$ = radians per unit time (i.e., 2π times the frequency).

$$v_y = r\omega \cos (\omega t + \epsilon) = \omega x$$

$$a_y = - r\omega^2 \sin (\omega t + \epsilon) = - \omega^2 y$$

For *SHM* of *H* in horizontal diameter:

$$x = r \cos (\theta + \epsilon) = r \cos (\omega t + \epsilon); \; v_x = - r\omega \sin (\omega t + \epsilon) = - \omega y$$

$$a_x = - r\omega^2 \cos (\omega t + \epsilon) = - \omega^2 x$$

If the time is reckoned from the instant when *V* is in its mid-position, and moving upward, $\epsilon = 0$. The three curves (Fig. 10) *OA*, *O′B*, and *OC* are the space-time, velocity-time, and acceleration-time curves, respectively, for one complete period of a simple harmonic motion; $\epsilon = 0$; *Ot* represents the period; the values of *y*, *v*, and *a* marked are for position *Q*, shown. In Fig. 8 the curve is the velocity-space curve, and the inclined line the acceleration-space curve. They show how *v* and *a* vary with the displacement of the moving point; thus for the position *Q*, *v* and *a* have values as marked.

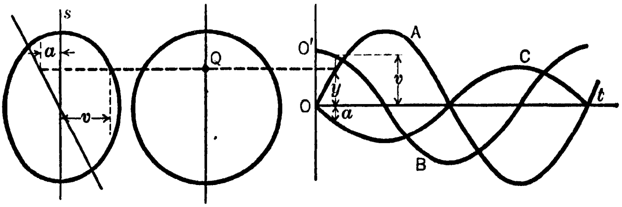

FIG. 8 FIG. 9 FIG. 10

From the above equations and curves, it will be noted that simple harmonic motion may be defined also as any rectilinear motion in which the acceleration is always directed toward a fixed point in the path and is proportional to the distance between that point and the moving point.†

---

* For curvilinear motion, this is tangential acceleration only.

† A common example of simple harmonic motion is the motion of a weight suspended from an elastic spring.

12. CURVILINEAR MOTION

Velocity. If s is distance measured along the curved path of a particle, then the magnitude of velocity (speed) at any instant $= \frac{ds}{dt}$; the linear direction of the velocity is tangent to the path at the instantaneous position of the particle; and the sense of the velocity corresponds to the direction of motion of the particle at the instant.

The velocity vector changes in magnitude and direction. In Fig. 11, let A, B, C represent positions of particle P in its curved path; s, distance along the path; and v_1, v_2, v_3, velocity vectors at A, B, C. Plot velocity vectors $O'A'$, $O'B'$, $O'C'$, etc., from any origin O' to represent the velocities at A, B, C, etc. The curve $A'B'C'$, drawn through the ends of the vectors, is called a *hodograph* for the motion. For every position of P in its path, there is a corresponding position P' in the hodograph; and P' describes distance s' on the hodograph while P describes distance s on the path. Vector $O'P'$ represents the velocity of P. In time Δt, P moves from A to C, its velocity changes from $O'A'$ to $O'C'$, and the velocity change is $A'C'$.

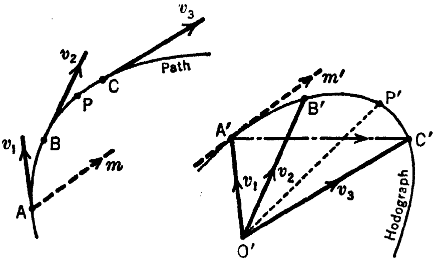

FIG. 11

Acceleration. Referring to the hodograph (Fig. 11), *average acceleration* for interval Δt, during which particle P moves from A to C, is vector $A'C'/\Delta t$, and it has the direction of the chord $A'C'$. The *instantaneous acceleration* of P at $A = a =$ limit of the average acceleration as Δt approaches zero.

$$a = \lim_{\Delta t \to 0} \left(\frac{\text{vector } A'C'}{\Delta t}\right) = \lim_{\Delta t \to 0} = \left(\frac{\text{arc } A'B'C'}{\Delta t}\right) = \frac{ds'}{dt} = \text{speed of } P'$$

on hodograph. The direction of a is along the tangent $A'm'$, and as P' is moving clockwise, the sense is as indicated by arrow at m'. Hence acceleration at A is Am, parallel to $A'M'$ and $= \frac{ds'}{dt}$. Its tangential component is $\frac{ds}{dt}$, and its normal component is $\frac{v^2}{\rho}$, ρ being the radius of curvature at A. *Unit of acceleration* is any velocity unit divided by any time unit.

Components of Velocity and Acceleration

Components of Velocity and Acceleration of a Particle for Any Curved Path (*not necessarily planar*). The position of the particle P being defined by its coordinates, x, y, z, the axial components of velocity are $v_x = \frac{dx}{dt}$, $v_y = \frac{dy}{dt}$, $v_z = \frac{dz}{dt}$. Resultant velocity $v = \sqrt{v_x^2 + v_y^2 + v_z^2}$, and its direction cosines are $\cos\theta_x = \frac{v_x}{v}$, $\cos\theta_y = \frac{v_y}{v}$, $\cos\theta_z = \frac{v_z}{v}$. Axial components of acceleration are:

$$a_x = \frac{dv_x}{dt} = \frac{d^2x}{dt^2}; \quad a_y = \frac{dv_y}{dt} = \frac{d^2y}{dt^2}; \quad a_z = \frac{dv_z}{dt} = \frac{d^2z}{dt^2}$$

Resultant acceleration $a = \sqrt{a_x^2 + a_y^2 + a_z^2}$; and its direction cosines are:

$$\cos\phi_x = \frac{a_x}{a}; \quad \cos\phi_y = \frac{a_y}{a}; \quad \cos\phi_z = \frac{a_z}{a}$$

The tangential and normal components of acceleration are $a_t = \frac{dv}{dt} = \frac{d^2s}{dt^2}$, and $a_n = \frac{v^2}{\rho}$, ρ being the radius of curvature. Resultant acceleration is

$$a = \sqrt{a_t^2 + a_n^2} = \sqrt{a_x^2 + a_y^2 + a_z^2}$$

If the path is a plane curve, $v_z = 0$ and $a_z = 0$.

The above discussion shows that velocities and accelerations (like forces) may be composed or resolved according to the parallelogram and parallelepipedon laws.

Motion of a Projectile

Projectile * Describing Plane Curvilinear Motion. In the following formulas air resistance is neglected; v_0 = velocity of projection; θ = angle of projection (Fig. 12); x and y = coordinates of the projectile at any time t after projection; v = velocity; v_x and v_y = x and y components respectively of v; r = range on the horizontal plane through O; θ_1 = value of θ for maximum r; h = greatest height attained; and T = time of flight. The path of the projectile, or the trajectory, is a parabola as represented, and a set of parametric equations for it are:

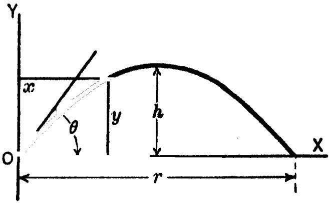

Fig. 12

$$x = v_0 \cos\theta \cdot t,\ y = v_0 \sin\theta \cdot t - \tfrac{1}{2} g t^2$$

from which

$$y = x \tan\theta - g x^2 / 2 v_0^2 \cos^2\theta$$

Also:

$$v_x = v_0 \cos\theta; \quad v_y = v_0 \sin\theta - gt; \quad v = \sqrt{v_0^2 - 2gy}; \quad h = \sin^2\theta \cdot v_0^2/2g;$$

$$r = \sin 2\theta \cdot v_0^2/g; \quad \theta_1 = 45°; \quad T = \frac{2 v_0 \sin\theta}{g}$$

If the direction of projection is horizontal, $\theta = 0$; the equation of the path is $y = -gx^2/2v_0^2$; and $x = v_0 t$, and $y = -\tfrac{1}{2} g t^2$.

The fact that the horizontal component of velocity is constant indicates that the hodograph of the motion of a projectile is a straight vertical line.

Motion Graphs

Motion Graphs similar to those previously discussed for rectilinear motion may be constructed for curvilinear motion of a particle. Great care must be exercised, however, in interpreting the significance of slopes, areas, and subnormals when acceleration or distance is involved. In this connection, reference should be made to the footnotes referred to in the previous discussion.

In general, accelerations obtained are tangential components only, while " displacements " must be replaced by " distances along the curve." Thus, in the velocity-time graph (Art. 11, Fig. 3), the slope of the curve represents the magnitude of the *tangential component* of the acceleration,† while the area under the curve represents the *distance along* the curve.

13. MOTIONS OF A BODY

Translation of a Rigid Body is a motion such that each straight line in it remains fixed in direction. The *paths* of all particles of the body are exactly alike, straight or curved (not necessarily plane curves); the *displacements* of all particles during a given time are the same; the *velocities* of all particles at any instant are the same; and their *accelerations* at any instant are the same. For these reasons, it is customary to use the expressions " velocity of the body " and " acceleration of the body." The motion is described by the same formulas as those previously derived for rectilinear and curvilinear motions of a particle.

Rotation of a Rigid Body is a motion such that one line of the body, or of its extension, remains fixed. The fixed line is the *axis*. The plane through the mass center perpendicular to the axis is the *plane of rotation*.

Plane Motion of a Rigid Body is a motion such that each particle of the body moves in a plane at a constant distance from a fixed plane through the mass center (called the *plane of motion*), while each line of the body parallel to the plane of motion turns through the same angle in the same time interval.

Three-dimensional Motion of a Rigid Body is a term covering all types of motion in three-dimensional space, including pure translation along a skewed curve as a special case. Even in the most general case, any three-dimensional motion of a rigid body may be regarded as consisting of two components: one, a translation equal to that of the mass center, and the other a rotation about some axis through the mass center.

---

* Rotation disregarded and body considered as a particle.

† However, if a velocity-time graph were made for motion along the hodograph of the original motion, the slope of the curve would represent the magnitude of the *total* acceleration of the original particle along the original path.

Angular Displacement of a Rigid Body is the change of angular position of any line in the plane of motion.

Angular Velocity of a Rigid Body is its time rate of angular displacement (i.e., rate of change of angular position).

Angular Acceleration of a Rigid Body is its time rate of change of angular velocity.

14. ROTATION

Angular Velocity. The paths of all particles are circles with centers on the axis. Since all lines of the body parallel to the plane of rotation sweep out equal angles in equal times, it is customary to describe rotation by the behavior of one radial line. In Fig. 13, let θ be the angle from the x axis to the radial line OP. $\Delta\theta = \theta_2 - \theta_1$ is the *angular displacement* of the body in the time $\Delta t = t_2 - t_1$, and is expressed in any angular unit. *Average angular velocity* = $\frac{\theta_2 - \theta_1}{t_2 - t_1} = \frac{\Delta\theta}{\Delta t}$. If the angle changes at a uniform rate, actual velocity at any time = $\Delta\theta/\Delta t$. For every case, the *instantaneous angular velocity* = $\omega = \lim_{\Delta t \to 0}\left(\frac{\Delta\theta}{\Delta t}\right) = \frac{d\theta}{dt}$. The sign depends on the numerator of the fraction, or the way in which θ is changing. The *unit of angular velocity* is any angular displacement unit divided by any time unit, such as radians per sec, rev per min, etc.

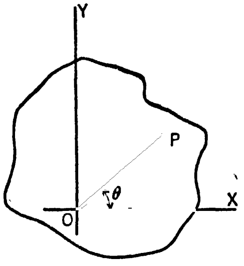

FIG. 13

Angular Acceleration. *Average angular acceleration* = $\frac{\omega_2 - \omega_1}{t_2 - t_1} = \frac{\Delta\omega}{\Delta t}$. If the angular velocity changes at a uniform rate, actual angular acceleration at any time = $\Delta\omega/\Delta t$. For every case, the *instantaneous angular acceleration* = $\alpha = \lim_{\Delta t \to 0}\left(\frac{\Delta\omega}{\Delta t}\right) = \frac{d\omega}{dt} = \frac{d^2\theta}{dt^2}$. The sign of α depends on the numerator of the fraction, or on the way in which ω is changing. The *unit of angular acceleration* is any angular velocity unit divided by any time unit, as radians per sec per sec (i.e., radians per sec^2), etc.

Formulas for Determination of α, ω, θ, t. The formulas are exactly analogous to those previously derived for rectilinear motion, a, v, and s being replaced by α, ω and θ, respectively. The formulas are:

$$\omega = \frac{d\theta}{dt}; \qquad \alpha = \frac{d\omega}{dt} = \frac{d^2\theta}{dt^2}; \qquad \frac{\alpha}{\omega} = \frac{d\omega}{d\theta}$$

$$\theta_2 - \theta_1 = \int_{t_1}^{t_2} \omega dt; \quad \omega_2 - \omega_1 = \int_{t_1}^{t_2} \alpha dt; \quad t_2 - t_1 = \int_{\theta_1}^{\theta_2} \frac{d\theta}{w} = \int_{\omega_1}^{\omega_2} \frac{dw}{\alpha}; \quad \omega_2^2 - \omega_1^2 = 2\int_{\theta_1}^{\theta_2} \alpha d\theta$$

Relations between Rectilinear and Angular Velocities and Accelerations. Let ω and α, respectively, be instantaneous angular velocity and acceleration of a rotating body, and v and a the corresponding instantaneous rectilinear velocity and acceleration of a point P of the body located at distance r from the axis of rotation. Then:

$$v = r\omega; \quad a_t = r\alpha; \quad a_n = r\omega^2; \quad a = r\sqrt{\alpha^2 + \omega^4}$$

Sense of v must agree with sense of ω, and sense of a_t with sense of α. Sense of a_n is always toward axis.

Motion Graphs

Motion Graphs analogous to those previously discussed for rectilinear motion may be constructed to show the relations between angular displacement, velocity and acceleration, and time. θ, ω, and α correspond to s, v, and a, respectively.

15. PLANE MOTION

Any displacement resulting from plane motion may be accomplished by a translation of the body which will bring any one line of it, which is perpendicular to the plane of motion, into final position, followed by a rotation of the body about that line into final position. The necessary amount of translation depends on the line of the body selected as axis of the rotation; the amount of the rotation does not. **The state of motion of a body at any instant may be regarded as consisting of two components, a translational motion and a rotational motion.** Thus a plane motion may be traced by giving the history of the movement of one point of the body (called a base point) in its own curved path, and a description of the rotation of the body about the selected base point.* The point selected as base should be one for which the motion is readily specified. For a wheel rolling along a straight path, the center would be selected as a base point.

Velocity of Any Point P of the body, at any instant, with respect to a fixed point O, is the vector sum of the velocity of base point A, with respect to O, and of the velocity of P with respect to A due to rotation about A. Thus (Fig. 14) O is the fixed point, A the moving base point, and P any other point of the body at distance r from A; v_1 is velocity of A with respect to O, and $v_2 = r\omega$ is velocity of P with respect to A. Resultant velocity of P with respect to $O = v$; or $v_{P \text{ to } O} = v_{P \text{ to } A} + v_{A \text{ to } O}$.

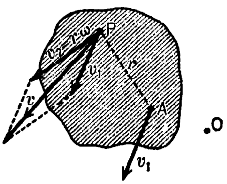

FIG. 14

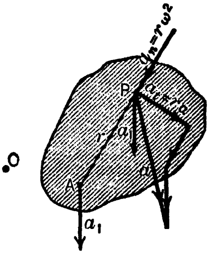

FIG. 15

Acceleration of Any Point P, with respect to a fixed point O, at any instant, has two components; one is that of the base point A with respect to O, and the other that of P with respect to base A. Acceleration of P with respect to A is rotational, and is conveniently replaced by its tangential and normal components, $a_t = r\alpha$ and $a_n = r\omega^2$. Then resultant acceleration of P, with respect to O, is the vector sum of $r\alpha$, $r\omega^2$, and acceleration of A with respect to O. Thus (Fig. 15) a_1 is acceleration of A to O; and acceleration P to A is resultant of a_t and a_n. Acceleration of P to O is a = vector sum of a_1, a_t, and a_n.

Instantaneous Axis. For a body having plane motion, there is always one point in it (or in its extension), at each instant, for which the velocity with respect to A (Fig. 14) is equal and opposite to velocity of A with respect to O; that is, its velocity is zero at the instant. This point Q is called the *instantaneous* (*or instant*) *center* of rotation, and a line through Q, perpendicular to the plane of motion, is called the *instantaneous axis*. Since Q is at rest for the instant, the resultant velocities of all points at the instant are purely rotational about the instant axis. The instant center is the intersection of two lines drawn from any two points, C and D, in the plane of the motion, perpendicular to their velocities. If the velocity of the point C is known, ω for the body is determined by dividing v_C by the distance of C from Q, or by r_C. The velocity of any other point E is $\omega \times r_E$, perpendicular to the radius r_E.

The position of Q in the body (or in its extension) is continually changing; its locus is a line (usually curved) fixed in the body and moving with it, called the *body centrode*. The locus of the positions of Q in the fixed plane of motion is a line (usually curved) called the *space centrode*. The plane motion may be considered as produced by the rolling, without slipping, of the body centrode upon the space centrode.

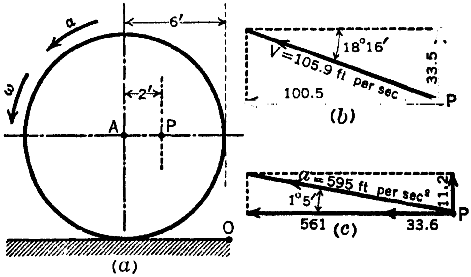

FIG. 16

Example: Rolling Wheel Describing Plane Motion. A wheel of 6-ft radius rolls along a straight horizontal path, and at a certain instant the point P, 2 ft from center of wheel, is in the position shown in Fig. 16a. At this instant ω = 16.75 radians per sec and α = 5.6 radians per sec². Deter-

---

* To simplify matters, "points" are referred to throughout this and the following discussion but "lines" through the points perpendicular to the plane of motion should be understood. Thus, in Figs. 14–15, the parallel lines through P, A, and O, perpendicular to the plane of motion, move relative to each other.

mine the velocity and acceleration of point P with respect to fixed point O at the specified instant. *Solution:* Select center A as base point. From relations between v and a of any point of a rotating body, and ω and α of the body:

$v_{A\text{ to }O} = r\omega = 6 \times 16.75 = 100.5$ ft per sec, horizontally toward left.
$v_{P\text{ to }A} = r\omega = 2 \times 16.75 = 33.5$ ft per sec, vertically upward.
Therefore, $v_{P\text{ to }O} = 105.9$ ft per sec, upward to left, at 18° 16′ to horizontal (Fig. 16*b*).
$a_{A\text{ to }O} = r\alpha = 6 \times 5.6 = 33.6$ ft per sec², horizontally toward left.
$a_{tP\text{ to }A} = r\alpha = 2 \times 5.6 = 11.2$ ft per sec², vertically upward.
$a_{nP\text{ to }A} = rw^2 = 2 \times (16.75)^2 = 561$ ft per sec², horizontally toward left.
Therefore, $a_{P\text{ to }O} = 595$ ft per sec², upward to left, at 1° 5′ to horizontal (Fig. 16*c*).

KINETICS

16. BASIC QUANTITIES

System of Units *

The Unit of Force is the *pound* of force and equals the pull of the earth on 1 lb of mass.

Since the mass of a body is absolutely constant but the pull of the earth on it varies with geographical location and altitude (i.e., varies as the acceleration of gravity varies), the pound of force is not an absolute unit, but its variation is too slight to be of importance in most practical problems.

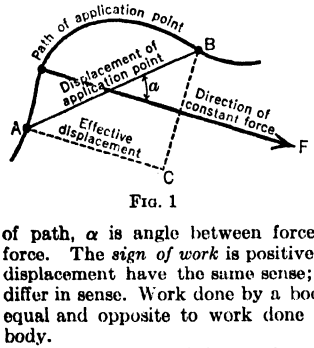
The Unit of Acceleration is the *foot per second per second* (abbreviated ft per sec²).

The Unit of Mass is the *slug* and equals the mass to which an acceleration of 1 ft per sec² would be given by the application of a 1-lb force. Unlike the pound of mass, it is not an absolute unit. Under standard conditions, 1 slug of mass = 32.1739 lb of mass (approx.).

The Relation between Force, Mass, and Acceleration of a particle, using the above system of units, is expressed by the formula $F = ma$ $\left(\text{or } F = \frac{W}{g}a\right)$, where F = force in pounds, m = mass in slugs (= weight W in pounds divided by acceleration of gravity in feet per second per second), and a = acceleration in the direction of the force in feet per second per second.†

17. DERIVED QUANTITIES AND RELATIONS

Work, Power, and Energy



Path of application point
B
Displacement of application point
α
Direction of constant force
A
Effective displacement
F
C

FIG. 1

Work of a Force, if constant, is the product of the force and the effective displacement of its application point. *Effective displacement* of application point is the component of the displacement parallel to the force. The body exerting the force is also said to do work. In Fig. 1, the work of force F as application point describes path $AB = F \times AC$. Since $F \cdot (AB \cos\alpha) = (F \cos\alpha) \cdot AB$, the work is also equal to displacement of application point times component of force parallel to the displacement. *Work of a variable force* in moving a body through distance $\Delta S = (s_2 - s_1)$ is $W = \int_{s_1}^{s_2} F \cos\alpha \, ds = \int_{s_1}^{s_2} F_t ds$, in which F is the variable force, ds is the elementary length of path, α is angle between force and element ds, and F_t is tangential component of force. The *sign of work* is positive if force and effective displacement have the same sense; it is negative if they differ in sense. Work done by a body against a force is equal and opposite to work done by the force on the body.

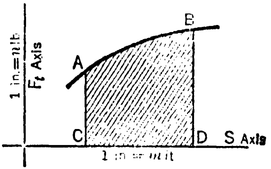


FIG. 2

The Unit of Work is any force unit times any distance unit (as foot-pound) or any power unit times any time unit (as watt-hour).

Work Diagram (Fig. 2). Plot values of F_t as ordinates; corresponding values of s as abscissas; draw curve AB through ends of ordinates. Area $ABDC$ times mn equals work, in foot-pounds, done by F_t over distance $s_2 - s_1$.

---

* The units herein defined are those of the English gravitational system. For a complete discussion of English and metric gravitational and absolute units, see Sec. III.

† With any system of units, $F = Kma$, where K is a constant. In this system $K = 1$.

Work of Gravity on a body in any motion equals product of weight and change in height of the mass center. ***Work of a central force*** F (one always directed toward a fixed point), in any displacement of its application point, is $\int_{r_1}^{r_2} F\,dr$, in which r_2 and r_1 are the distances of the application point from the center at the beginning and end of the displacement.

Work of a Torque T on a rotating body for an angular displacement of $\theta = (\theta_2 - \theta_1)$ radians is $W = \int_{\theta_1}^{\theta_2} T\,d\theta$. If T is constant, $W = T(\theta_2 - \theta_1)$.

Mechanical Efficiency of a machine is the ratio of useful output to total input of work. Let W_u = useful work performed, W_f = useless work required to overcome friction or air or any other type of resistance, W_a = work applied to the machine. Then $W_a = Wu + W_f$, and Mechanical Efficiency $= \dfrac{W_u}{W_a}$.

Power of a Force is its time rate of doing work. The body exerting the force is also said to have power. Let P = power and W = work. Then instantaneous $P = \dfrac{dW}{dt} = F_t \dfrac{ds}{dt} = F_t v$, where v is instantaneous velocity of application point of force F.

The Unit of Power is any work unit divided by any time unit (as foot-pound per second). One horsepower = 550 ft-lb per sec = 33,000 ft-lb per min = 0.7457 kilowatt.

Power of a Torque at any instant is $P = \dfrac{dW}{dt} = T\dfrac{d\theta}{dt} = T\omega$ where ω is instantaneous angular velocity of the body.

Energy * of a *body* (or system of bodies) is the amount of work it can do, by virtue of its motion or position, against forces applied to it, while changing to a standard state.

Potential energy (PE) of a body is that possessed by virtue of its configuration. Thus, a body of weight W, located at a height above the earth's surface such that its mass center can descend h feet, has a potential energy $PE = Wh$.

Kinetic energy (KE) of a body is that possessed by virtue of its velocity, and the standard state is zero velocity. KE of a *body in translation* $= {}^1/_2 mv^2$. KE of a *rotating body* $= {}^1/_2 I\omega^2 = {}^1/_2 mk^2\omega^2$, I, k, and ω being moment of inertia, radius of gyration, and angular velocity, respectively, about axis of rotation. KE of a body having plane motion $= {}^1/_2 I\omega^2 = {}^1/_2 mk^2\omega^2 = {}^1/_2 m\bar{v}^2 + {}^1/_2 \bar{I}\omega^2$, in which I and k are referred to instantaneous axis, $\bar{v}$ = velocity of mass center, and $\bar{I}$ = moment of inertia about axis through mass center perpendicular to plane of motion. *Unit of energy* is same as unit of work. For KE in foot-pounds, use m in slugs, v in feet per second, ω in radians per second, and k in feet.

Principle of Conservation of Energy. If a body or system of bodies is isolated so that it neither receives nor gives out energy, its total store of energy, all forms included, remains constant; there may be a transfer of energy from one part of the system to another, but the total gain or loss in one part is exactly equivalent to the loss or gain in the remainder. This is the *principle of conservation of energy*.

Principle of Work and Kinetic Energy. Total work of the applied forces acting on any body, or on any system of connected bodies, equals the change in the kinetic energy of the body, or bodies. (This assumes no work converted into non-mechanical types of energy.) Work done $= \Delta KE$. ΔKE in translation $= {}^1/_2 m(v^2{}_2 - v_1{}^2)$, v_1 and v_2 being initial and final velocities. ΔKE in rotation $= {}^1/_2 I(\omega^2{}_2 - \omega_1{}^2) = {}^1/_2 mk^2(\omega_2{}^2 - \omega_1{}^2)$, ω_1 and ω_2 being initial and final angular velocities. In plane motion, change in KE is

$$\begin{aligned}\Delta KE = {}^1/_2 I(\omega_2{}^2 - \omega_1{}^2) = {}^1/_2 mk^2(\omega_2{}^2 - \omega_1{}^2) &= {}^1/_2 m(\bar{v}_2{}^2 - \bar{v}_1{}^2) + {}^1/_2 \bar{I}(\omega_2{}^2 - \omega_1{}^2)\\ &= {}^1/_2 m(\bar{v}_2{}^2 - \bar{v}_1{}^2) + {}^1/_2 m\bar{k}^2(\omega_2{}^2 - \omega_1{}^2)\end{aligned}$$

in which I and k are referred to instantaneous axis, $\bar{I}$ and $\bar{k}$ to a parallel axis through mass center, and $\bar{v}$ is velocity of mass center.

Example. Water falling from a height of 120 ft at the rate of 1000 cu ft per min drives a turbine directly connected to an electric generator at 120 rpm. If the total resisting torque due to friction is 250 lb-ft, and the water leaves the turbine blades with a velocity of 15 ft per sec, find the power developed by the generator.

This is a problem in the conversion of potential energy to work which in turn is converted to useful kinetic energy, wasted kinetic energy, and wasted thermal energy, the total energy of the system of course remaining constant. Assume that 1 cu ft of water weighs 62.5 lb and $g = 32$ ft per sec.^{2} In 1 min:

$$\Delta PE = Wh = 1000 \times 62.5 \times 120 = 7{,}500{,}000 \text{ ft-lb}$$

$$\text{Wasted } \Delta KE = {}^1/_2\, mv^2 = \frac{1000 \times 62.5 \times 15^2}{2 \times 32} = 219{,}700 \text{ ft-lb}$$

---

* Mechanical energy (which includes potential and kinetic energy) is referred to in this definition. There are other forms of energy such as thermal, chemical, and electrical.

Wasted Friction (Thermal) $\Delta TE = T\theta = 250 \times 2\pi \times 120 = 188{,}500$ ft-lb

Therefore Useful $\Delta KE = \Delta PE -$ **Wasted** $\Delta KE -$ **Wasted** ΔTE

$= 7{,}500{,}000 - 219{,}700 - 188{,}500 = 7{,}091{,}800$ ft-lb

$P = 7{,}091{,}800/33{,}000 = 215$ hp or $215 \times 0.7457 = 160$ kw

Impulse, Momentum, and Impact

Linear Impulse of a constant force F for time $t = F \times t$. If the force varies in magnitude and direction, the impulse is computed from axial components of impulse; and the axial components of impulse are found by taking the time integrals of axial components of the force. The three axial component impulses are $\int_{t_1}^{t_2} F_x\, dt$, $\int_{t_1}^{t_2} F_y\, dt$, $\int_{t_1}^{t_2} F_z\, dt$; the resultant of these is the impulse of the force F. Impulse is a *vector quantity*; hence the impulse of the force equals the square root of the sum of the squares of the components. The direction cosines of the resultant vector are determined in the usual manner. *Unit of impulse* is any unit force times any unit time, as pound (force) seconds.

Angular Impulse of a force about a line for a time interval dt is the product of the moment of the force about the line and the time dt. If T represents the moment or torque of the force, the angular impulse for the time interval $(t_2 - t_1)$ is $\int_{t_1}^{t_2} T dt$. *Unit of angular impulse* is unit torque times unit time, as pound (force) feet seconds.

Sign of Impulse. Impulse of a force tending to increase velocity of the body to which the force is applied is positive; that which tends to decrease velocity is negative.

Linear Momentum of a *particle* is the product of its mass and velocity. It is a vector quantity and has the *sense* and *direction* of the velocity. *Unit of momentum* is the same as unit of impulse. Linear momentum of a *body* is the resultant, or vector sum, of the momentums of its particles. In any motion the linear momentum of a body is $m\bar{v}$, m being mass of the body and $\bar{v}$ the velocity of its mass center.

Angular Momentum of a *particle* about an axis is the moment of its momentum about that axis. In Fig. 3, let mv = momentum of particle P. Resolve the momentum into components parallel and perpendicular to the axis. DE is perpendicular distance from axis to line AP. The angular momentum of $P = mv \cos \alpha \times DE$. The angular momentum of a *body* about an axis is the algebraic sum of the angular momentums of its particles. The angular momentum of a rotating body about the axis of rotation is $I\omega = mk^2\omega$, I and k being moment of inertia and radius of gyration respectively about the axis of rotation, and ω the angular velocity. *Unit of angular momentum* is same as unit of angular impulse.

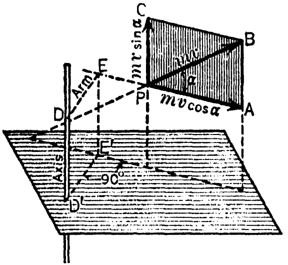

FIG. 3

Principle of Conservation of Linear and Angular Momentum. When no external forces are acting upon a body or system of bodies, the component linear momentum along any line and the angular momentum about any line remain constant; this is the *principle of conservation of linear and angular momentum.* (This assumes no conversion of work into non-mechanical energy.)

Principle of Impulse and Momentum. For *linear momentum*, the impulse of the resultant force acting for an infinitesimal time upon a body is equal to the change in linear momentum of its mass center during that time parallel to the direction of the force. Referred to coordinate axes, the change in the component of linear momentum parallel to any axis x for any length of time $t_2 - t_1$ equals the algebraic sum of the components of the impulses of the applied forces parallel to the axis in the same time, or, more briefly, $\Delta(m\bar{v}_x) = \sum \int_{t_1}^{t_2} F_x dt$. Similarly, the change in the *angular momentum* about any axis y in the time $t_2 - t_1$ equals the algebraic sum of the angular impulses of the applied forces about the axis in the same time, or, more briefly, $\Delta(I_y\omega) = \sum \int_{t_1}^{t_2} T_y dt$.

Example. A jet of water strikes a concave vessel with a velocity of 80 ft per sec and leaves it with a velocity which has the same magnitude but makes an angle of 120° with the original direction. If the diameter of the jet is 1 in., find the force necessary to hold the vessel in position.

The sustaining force F must bisect the acute angle between the lines representing the original and final velocities. Let the line of action of F (Fig. 4) be taken as the X axis. There is no change in the Y component of momentum. The impulse of the force in the X direction in t seconds = $F \times t$ pound-seconds. The weight of water deflected in t seconds is $W = 80\pi \times 62.5t/576$ pounds. The component of original momentum in the X direction = $-80W \cos 30°/g$ pound-seconds. The component of final momentum in the X direction = $80W \cos 30°/g$ pound-seconds. The change in momentum in the X direction = $160W \cos 30°/g$ = $5W \cos 30°$ pound-seconds. The fundamental relation gives $F \times t = 5 \times 80\pi \times 62.5 \times \cos 30° \times t/576$, whence F = 118 lb. Observe that the sustaining force F does no mechanical work and that the water suffers no loss of kinetic energy.

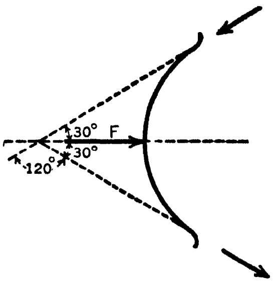

FIG. 4

Impact occurs when two bodies collide. It is *direct* when the motion is perpendicular to the striking surfaces; otherwise it is *oblique*. It is *central* if the forces which the bodies exert on each other are directed along the line joining the mass centers; otherwise it is *eccentric*. In any collision, the forces which the two bodies exert on each other are equal and opposite at each instant; hence the total impulses of these forces during the collision are equal and opposite, and according to the principle of impulse and momentum the changes in the momentums of the bodies produced by the collision must be equal and opposite; or, otherwise stated, the total momentum of the two bodies is unchanged by the collision. Or, for *direct central impact*:

$$m_1v_1 + m_2v_2 = m_1V_1 + m_2V_2$$

wherein m_1 and m_2 = the masses of the bodies, v_1 and v_2 their velocities before, and V_1 and V_2 their velocities after, the collision; but in numerical substitution, velocities in one direction are given the same sign and those in the other direction the opposite sign.

Experiments on direct central impact of spherical bodies have shown that the relative velocities of spheres after impact are always less than before the impact and that these relative velocities are opposite in direction. The ratio of the relative velocities after impact to that before impact is called *coefficient of restitution*; it seems to depend only on the material of the impinging spheres. For glass the coefficient is $^{15}/_{16}$, for steel and cork $^5/_9$, ivory $^8/_9$, wood about $^1/_2$, clay and putty 0. If e = the coefficient, then

$$(V_1 - V_2) = -e(v_1 - v_2)$$

This equation and the preceding one solved simultaneously show that

$$V_1 = v_1 - \frac{(1+e)m_2}{m_1 + m_2}(v_1 - v_2); \quad V_2 = v_2 - \frac{(1+e)m_1}{m_1 + m_2}(v_2 - v_1)$$

During impact there is, in general, loss of kinetic energy; * the loss is

$$^1/_2(v_1 - v_2)^2(1 - e^2)m_1m_2/(m_1 + m_2).$$

Bodies for which $e = 0$ are said to be *inelastic*; and those for which e is nearly 1 are said to be nearly perfectly *elastic*. When a sphere is dropped on a horizontal surface of a large body from a height h, if H = the height of rebound, then $H = e^2h$. This equation furnishes a means of computing e.

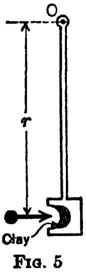

FIG. 5

Example. Ballistic Pendulum. This is a device for determining the velocity of a bullet. The bullet is imbedded in soft material, such as clay, for which $e = 0$. Referring to Fig. 5, let m_1 = mass of bullet, m_2 = mass of pendulum, k = radius of gyration about axis of suspension O, v_1 = velocity of bullet (to be determined), $v_2 = r\omega$ = velocity of bullet after impact, ω = angular velocity of pendulum after impact, and assume pendulum stationary before impact. Then angular momentum of system before impact = m_1v_1r, and angular momentum of system just after impact = $m_1r^2\omega + m_2k^2\omega$. Since total momentum of system remains constant, $m_1v_1r = m_1r^2\omega + m_2k^2\omega$. If mass center of pendulum rises to height h, $k^2\omega^2 = 2gh$. Combining last two equations to eliminate ω and solving for v_1, $v_1 = (m_1r^2 + m_2k^2)\sqrt{2gh}/m_1rk$. The quantities on the right-hand side of this equation are easily determined experimentally.

18. KINEMATIC AND KINETIC FORMULAS

Symbols. s = distance along path of motion; x, y, z = coordinates of any point; $\bar{x}, \bar{y}, \bar{z}$ = coordinates of mass center; t = time; a = resultant linear acceleration of any point; $\bar{a}$ = resultant

---

* As energy can be neither created nor destroyed, the total energy remains constant. The "lost" kinetic energy is simply converted into other forms, as into work done in distorting the bodies, thermal (heat) energy, etc.

linear acceleration of mass center; $a_{x,y,z}$ = components of resultant acceleration along x, y, z axes; a_t = resultant tangential acceleration of any point; a_n = resultant normal acceleration of any point; v, $\bar{v}$, $v_{x,y,z}$ = linear velocities having corresponding significances; θ = angular displacement; α = angular acceleration; ω = angular velocity; n = revolutions per unit time; r = radius (of curvature); g = acceleration of gravity = 32.2 ft per sec² (approx.); m = weight/g = mass; F = resultant force; $F_{x,y,z}$ = components of resultant force along x, y, z axes; F_t = resultant tangential force; F_n = resultant normal force; W = work; Eff = efficiency; P = power; KE = kinetic energy; Imp = linear impulse; Mom = linear momentum; T = resultant torque about axis of rotation; $T_{x,y,z}$ = torques about x, y, z axes; $Ang\ Imp$ = angular impulse; $Ang\ Mom$ = angular momentum; I = moment of inertia (for mass) about axis of rotation; $I_{x,y,z}$ = moments of inertia about x, y, z axes; $\bar{I}$ = moment of inertia about axis through mass center; $k, k_{x,y,z}$, $\bar{k}$ = corresponding radii of gyration; d = distance between axes; U = product of inertia; U_{xy} = product of inertia with respect to YOZ and ZOX planes; (U_{yz}, U_{zx} have corresponding significances); Δ indicates " change in."

Gravitation and Inertia Functions. Mass center has coordinates:

$$\bar{x} = \frac{\int xdm}{m}; \qquad \bar{y} = \frac{\int ydm}{m}; \qquad \bar{z} = \frac{\int zdm}{m}.$$

$$\bar{I} = \int r^2dm; \ \bar{k} = \sqrt{\bar{I}/m}; \ I = \bar{I} + md^2; \ k = \sqrt{I/m}; \ k^2 = \bar{k}^2 + d^2;$$

$$U_{xy} = \int xydm; \qquad U_{yz} = \int yzdm; \qquad U_{zx} = \int zxdm.$$

Translation—(Rectilinear Motion) *

$$v = \frac{ds}{dt}; \qquad a = \frac{dv}{dt} = \frac{d^2s}{dt^2}; \qquad \frac{a}{v} = \frac{dv}{ds};$$

$$\Delta s = \int_{t_1}^{t_2} vdt; \qquad \Delta v = \int_{t_1}^{t_2} adt; \quad \Delta t = \int_{s_1}^{s_2} \frac{ds}{v} = \int_{v_1}^{v_2} \frac{dv}{a}; \quad \Delta v^2 = 2\int_{s_1}^{s_2} ads;$$

$$F = m\bar{a}; \qquad \Delta W = \int_{s_1}^{s_2} Fds; \ KE = 1/2\, m\bar{v}^2; \qquad \Delta W = \Delta KE;$$

$$P = \frac{dW}{dt} = Fv; \qquad \Delta Imp = \int_{t_1}^{t_2} Fdt; \ Mom = m\bar{v}; \qquad \Delta Imp = \Delta Mom.$$

Translation—(Curvilinear Motion) *

$$v = \frac{ds}{dt}; \qquad v_x = \frac{dx}{dt}; \ v_y = \frac{dy}{dt}; \ v_z = \frac{dz}{dt}; \qquad v = \sqrt{v_x^2 + v_y^2 + v_z^2};$$

Directional cosines of v are: $\cos\theta_x = \frac{v_x}{v}$; $\cos\theta_y = \frac{v_y}{v}$; $\cos\theta_z = \frac{v_z}{v}$.

$$a_x = \frac{dv_x}{dt} = \frac{d^2x}{dt^2}; \qquad a_y = \frac{dv_y}{dt} = \frac{d^2y}{dt^2}; \qquad a_z = \frac{dv_z}{dt} = \frac{d^2z}{dt^2}; \qquad a = \sqrt{a_x^2 + a_y^2 + a_z^2};$$

Directional cosines of a are: $\cos\phi_x = \frac{a_x}{a}$; $\cos\phi_y = \frac{a_y}{a}$; $\cos\phi_z = \frac{a_z}{a}$;

$$a_t = \frac{dv}{dt} = \frac{d^2s}{dt^2}; \qquad a_n = \frac{v^2}{r}; \qquad a = \sqrt{a_t^2 + a_n^2}; \qquad \frac{a_t}{v} = \frac{dv}{ds};$$

$$\Delta s = \int_{t_1}^{t_2} vdt; \qquad \Delta v = \int_{t_1}^{t_2} a_tdt; \ \Delta t = \int_{s_1}^{s_2} \frac{ds}{v} = \int_{v_1}^{v_2} \frac{dv}{a_t}; \quad \Delta v^2 = 2\int_{s_1}^{s_2} a_tds;$$

$$F = m\bar{a}; \qquad F_x = m\bar{a}_x; \quad F_y = m\bar{a}_y; \quad F_z = m\bar{a}_z; \quad F = \sqrt{F_x^2 + F_y^2 + F_z^2};$$

$$F_t = m\bar{a}_t; \qquad F_n = m\bar{a}_n; \qquad F = \sqrt{F_t^2 + F_n^2};$$

$$\Delta W = \int_{s_1}^{s_2} F_tds; \qquad KE = 1/2\, m\bar{v}^2; \qquad \Delta W = \Delta KE; \qquad P = \frac{dW}{dt} = F_tv;$$

$$\Delta Imp_x = \int_{t_1}^{t_2} F_xdt; \qquad \Delta Imp_y = \int_{t_1}^{t_2} F_ydt; \qquad \Delta Imp_z = \int_{t_1}^{t_2} F_zdt;$$

$$Imp = \sqrt{Imp_x^2 + Imp_y^2 + Imp_z^2};$$

---

* For a rigid body in translation, accelerations and velocities of all particles are equal. However, $\bar{a}$ and $\bar{v}$ are indicated in certain of the kinetic translation formulas to make them applicable also to non-rigid bodies.

$$Mom_x = m\bar{v}_x; \qquad Mom_y = m\bar{v}_y; \qquad Mom_z = m\bar{v}_z;$$

$$Mom = \sqrt{Mom_x^2 + Mom_y^2 + Mom_z^2};$$

$$\Delta Imp_x = \Delta Mom_x; \; \Delta Imp_y = \Delta Mom_y; \; \Delta Imp_z = \Delta Mom_z; \quad \Delta Imp = \Delta Mom;$$

Directional Cosines of $\Delta Imp = \Delta Mom$ are: $\cos\psi_x = \dfrac{\Delta\bar{v}_x}{\Delta v}$; $\cos\psi = \dfrac{\Delta\bar{v}_y}{\Delta\bar{v}}$; $\cos\psi_z = \dfrac{\Delta\bar{v}_z}{\Delta\bar{v}}$.

For kinetic formulas applying to a translated *body* for rotation about an axis not fixed in the body or its extension, use formulas applying to " Rotation of a *Particle* " about its axis, considering entire mass of body as concentrated at the mass center.

Rotation †

$$\omega = \frac{d\theta}{dt}; \qquad \alpha = \frac{d\omega}{dt} = \frac{d^2\theta}{dt^2}; \qquad \frac{\alpha}{\omega} = \frac{d\omega}{d\theta};$$

$$\Delta\theta = \int_{t_1}^{t_2} \omega dt; \qquad \Delta\omega = \int_{t_1}^{t_2} \alpha dt; \quad \Delta t = \int_{\theta_1}^{\theta_2} \frac{d\theta}{\omega} = \int_{\omega_1}^{\omega_2} \frac{d\omega}{\alpha}; \quad \Delta\omega^2 = 2\int_{\theta_1}^{\theta_2} \alpha d\theta.$$

For a "Particle" ($\bar{I}$ *infinitesimal* **compared with I) :**

$$s = r\theta; \qquad v = r\omega; \qquad a_t = r\alpha; \qquad a_n = r\omega^2; \qquad a = r\sqrt{\alpha^2 + \omega^4};$$

$$T = F_t r = mr^2\alpha; \qquad F_t = mr\alpha; \quad F_n = mr\omega^2; \; F = mr\sqrt{\alpha^2 + \omega^4};$$

$$\Delta W = \int_{\theta_1}^{\theta_2} T d\theta; \qquad KE = 1/2\, mr^2\omega^2; \qquad \Delta W = \Delta KE; \qquad P = \frac{dW}{dt} = T\omega;$$

$$\Delta Ang\ Imp = \int_{t_1}^{t_2} T dt; \qquad Ang\ Mom = mr^2\omega; \quad \Delta Ang\ Imp = \Delta Ang\ Mom.$$

For a Body:

$$T = I\alpha = mk^2\alpha; \quad \Delta W = \int_{\theta_1}^{\theta_2} T d\theta; \quad \Delta W = \Delta KE; \quad P = \frac{dW}{dt} = T\omega;$$

$$KE = 1/2\, I\omega^2 = 1/2\, mk^2\omega^2;$$

$$\Delta Ang\ Imp = \int_{t_1}^{t_2} T dt; \quad Ang\ Mom = I\omega = mk^2\omega; \quad \Delta Ang\ Imp = \Delta Ang\ Mom.$$

Constrained Rotation *

Plane of rotation fixed above and parallel to horizontal *XZ* plane; vertical *Y* axis of rotation not passing through mass center (except as special case).

All previous rotation formulas apply if T is replaced by T_y. Additional formulas are:

For a Particle ($\bar{I}$ *infinitesimal* **compared with I) :**

$$F_x = mz\alpha - m\bar{x}\omega^2; \quad F_y = 0; \quad F_z = -m\bar{x}\alpha - m\bar{z}\omega^2; \qquad F = \sqrt{F_x^2 + F_y^2 + F_z^2};$$

$$T_x = F_z\bar{y} = -m\overline{xy}\alpha - m\overline{yz}\omega^2; \quad T_y = F_x\bar{z} = m\overline{z^2}\alpha - m\overline{xz}\omega^2 = mr^2\alpha$$

$$= -F_z\bar{x} = m\overline{x^2}\alpha + m\overline{zx}\omega^2 = mr^2\alpha;$$

$T_z = -F_x\bar{y} = -m\overline{yz}\alpha + m\overline{xy}\omega^2$; ($\theta$, ω, α positive for counterclockwise rotation facing origin from plus point on axis).

For a Body:

$T_x = -U_{xy}\alpha - U_{yz}\omega^2$; $T_y = I_y\alpha$; $T_z = -U_{yz}\alpha + U_{xy}\omega^2$ (Sign convention as above).

Center of Percussion and Center of Oscillation of a pendulum are located at distance from center of suspension $= k^2/\bar{z}$, where $\bar{z}$ is distance from center of suspension to mass center.

Plane and Three-Dimensional Motions

For Translation of Mass Center:

Consider entire mass as concentrated at mass center. Refer motion to set of fixed axes located outside the body. To determine acceleration of mass center, apply formulas for translation.

---

* In obtaining total forces and torques, effect of weight of body (this effect depending on position of plane of rotation) must not be neglected.

† Formulas are for rigid bodies.

For Rotation about Mass Center:

Consider mass center as fixed and resultant of forces as a couple. Refer motion to set of central principal axes. To determine components of angular acceleration about these axes, use formulas:

$$T_x = I_x\alpha_x + (I_z - I_y)\omega_y\omega_z; \quad T_y = I_y\alpha_y + (I_x - I_z)\omega_z\omega_x; \quad T_z = I_z\alpha_z + (I_y - I_x)\omega_x\omega_y$$

For Complete Resultant Motion:

Combine motion of translation of mass center with motion of rotation about mass center.

Work and kinetic energy changes also are equal to the respective sums of the corresponding changes under the above component motions.

19. TRANSLATION

Kinetic Formulas for motion of translation follow directly from the kinematic formulas applying to such motion and the previous discussion on kinetic quantities and their relations. The formulas are summarized in Art. 18 (p. 4-38) under the heading "Translation." For the solution of a specific problem, careful choice of formulas will often facilitate the computations. As there is no rotation, the resultant force acts through the mass center and there is no couple.

Example. Motion of Parallel Rod of a Locomotive. The problem is to find the forces acting upon the parallel rod when it is in any position with respect to the wheels. Assume velocity of locomotive constant at 60 miles per hour on a level track; driver diameter 5.5 ft; crank length 1 ft; and weight of rod 275 lb. The forces acting on the rod are its weight and the pressures of the crank pins at its ends; the latter are represented (Fig. 6) by their horizontal and vertical components. Since the resultant of all these forces acts through the mass center, $V_1 = V_2$; also $2V_1 - 275 = (W/g)a_y = 8.55a_y$ and $H_1 - H_2 = (W/g)a_x = 8.55a_x$. To determine a_x and a_y: The velocity of the center of either crank pin relative to the locomotive is $(88 \times 1)/2.75 = 32$ ft per sec (60 mi per hr = 88 ft per sec), and the relative motion of the pin being circular at constant velocity, the relative acceleration is toward the center of the crank-pin circle at all times and equals $32^2/1 = 1024$ ft per sec per sec. This is also the absolute acceleration of the crank pin, since the locomotive is assumed to have no acceleration. But the rod has the same acceleration as the crank pin; hence $a_x = 1024 \sin \theta$, and $a_y = 1024 \cos \theta$. Thus $V = 1/2\ (8755 \cos \theta + 275)$, and $H_1 - H_2 = 8755 \sin \theta$. In the lowest position of the rod, $\theta = 0$, $a_x = 0$, $a_y = 1024$, $H_1 = H_2$, $V = 1/2\ (8755 + 275) = 4515$. In a mid-position when $\theta = 90°$, $a_x = 1024$, $a_y = 0$, $H_1 - H_2 = 8755$, and $V = 1/2\ (275) = 137.5$. In the highest position, $\theta = 180°$, $a_x = 0$, $a_y = -1024$, $H_1 = H_2$, and $V = 1/2\ (275 - 8755) = -4240$, the negative sign meaning that V acts downward on the rod.

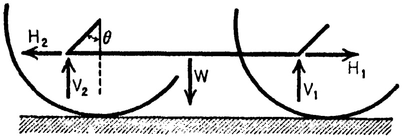

FIG. 6

20. ROTATION

Kinetic Formulas for motion of rotation follow directly from the kinematic formulas applying to such motion and the previous discussion on kinetic quantities and their relations. The formulas are summarized in Art. 18 (p. 4-39) under the heading "Rotation." For the solution of a specific problem, careful choice of formulas will often facilitate the computations. As there is no translation, the resultant force is zero but there is a couple.

Example. A Punch is required to exert a force of 100,000 lb through a distance of 1/4 in., and the work is to be supplied by a flywheel of radius of gyration = 1.5 ft making 120 rpm. Find the weight of the wheel, if the speed is not to be reduced below 100 rpm.

$\omega_1 = 120$ rpm $= 4\pi$ rad per sec, $\omega_2 = 100$ rpm $= (10/3)\pi$ rad per sec. Work done by punch $= 100{,}000/48$ ft-lb = reduction in KE of flywheel.

Change in $KE = 1/2\ mk^2\Delta\omega^2 = W \times 2.25\ (\omega_1{}^2 - \omega_2{}^2)/64 = W \times 2.25\ (\omega_1 - \omega_2)(\omega_1 + \omega_2)/64$.
Hence $\dfrac{W \times 2.25}{64}(2\pi/3)(22\pi/3) = \dfrac{100{,}000}{48}$, whence $W = 1230$ lb = minimum weight of flywheel.

Constrained Rotation

Constrained Rotation refers to rotation of a body about a fixed axis which does not pass through its mass center. Such an axis, since it constrains the motion,* must be held by forces (exerted by bearings) to keep it from shifting position. These bearing reactions depend upon the weight of the body, the manner in which the mass of body is distributed about the axis, the applied forces, the angular velocity ω, and the angular acceleration α. Generally, the resultant of the applied forces for such a body is not a single force, but a single force at a selected origin and a couple. Selecting the origin on the axis of rotation, the axial components of the single force and axial components of the couple are given by the following six equations.*

---

* In certain cases, the "physical path" itself constrains the rotation, as the action of the track on a train rounding a curve.

$$\begin{aligned} &\Sigma F_x = m\bar{z}\alpha - m\bar{x}\omega^2 && \Sigma T_x = -\alpha\int xydm - \omega^2\int yzdm = -U_{xy}\alpha - U_{yz}\omega^2 \\ &\Sigma F_y = 0 && \Sigma T_y = I_y\alpha \\ &\Sigma F_z = -m\bar{x}\alpha - m\bar{z}\omega^2 && \Sigma T_z = -\alpha\int yzdm + \omega^2\int xydm = -U_{yz}\alpha + U_{xy}\omega^2 \end{aligned}$$

In these equations, the axis of rotation is fundamentally the y axis; $\bar{x}$, $\bar{y}$, and $\bar{z}$ are the instantaneous coordinates of the mass center; ΣF_x, ΣF_y, ΣF_z are the sums of components of all applied forces in the axial directions; ΣT_x, ΣT_y, ΣT_z are the sums of moments of all applied forces about the axes; and the convention of signs for moments of forces, and senses of θ, ω, and α are that counterclockwise rotation, facing the origin from any plus point on an axis, is positive.

The equations are simultaneous at each instant. They are used more often to determine the forces exerted by the bearings on the axle, than to determine the resultant.

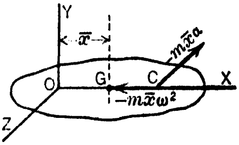

FIG. 7

Special Cases (Fig. 7). Choose the x axis through an instantaneous location of the mass center and let XZ be a plane of symmetry of a homogeneous body. The resultant is a single force in the plane of symmetry having the Z component $- m\bar{x}\alpha$ and the X component $- m\bar{x}\omega^2$ acting at point C. $\overline{OC} = k_y^2/\bar{x}$, k_y being radius of gyration about y axis. If $\bar{x} = 0$, the resultant becomes a couple in the XZ plane, of moment $= \Sigma T_y = I_y\alpha$. If $\alpha = 0$ and $\bar{x} \neq 0$, the resultant $= - m\bar{x}\omega^2$, in the sense CO. If $\alpha = 0$ and $\bar{x} = 0$, the resultant vanishes.

Centrifugal Force. Let any particle of mass m move in a circular path of radius r about a fixed y axis. The resultant of all forces acting on the particle has a normal component $= mr\omega^2$, and a tangential component $= mr\alpha$. The component $mr\alpha$ increases or decreases the speed of the particle; the component $mr\omega^2$ continually changes the direction of the linear velocity. The resultant of such forces for all the particles of the body is equivalent to the resultant specified by the general equations above. If ω is constant and $\alpha = 0$, the resultant force acting on the particle to make it rotate in its circular path is $mr\omega^2$ toward the axis, and is called *centripetal force*. *Centrifugal force* for the particle is equal and opposite to centripetal force, and is exerted by the particle upon its neighboring particles, or upon the axis of rotation. *Centrifugal resultant* for a body is the resultant of the centrifugal forces of all its particles. Generally, this resultant is not a single force; it may be computed from the general equations by making $\alpha = 0$ and reversing senses of resultant force and couple.

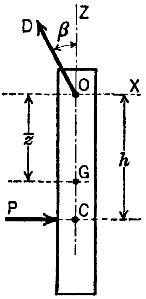

FIG. 8

Center of Percussion. A prismatic bar (Fig. 8) is suspended on a horizontal y axis at O. G is the mass center. If a force P, parallel to x axis, is applied to the body, the axle reaction OD will generally be inclined to the z axis at some angle $\pm\beta$, the angle depending on the distance h of P from the axis of rotation. If $h = k_y^2/\bar{z}$, in which k_y is radius of gyration about y axis, P will cause no x component of axle reaction; that is, β will be zero, and the point C, where the action line of P intersects OG, is the *center of percussion*. In impact-testing machines, heavy pendulums are used to deliver blows, and proper design requires the striking point to coincide with the center of percussion in order to avoid shock to the axle and detrimental vibration of the pendulum itself.

Examples of Constrained Rotation

A Simple Pendulum consists of a small heavy bob on a light string (Fig. 9).† The forces acting on it are the weight, W, and tension, T. The resultant force along the tangent $= - W \sin\theta$; the resultant force along the normal $= T - W\cos\theta$. The force equations are $Wa_t/g = - W\sin\theta$, $Wa_n/g = T - W\cos\theta$. Since $a_n = l\omega^2$, tension $T = W\left(\cos\theta + \frac{l\omega^2}{g}\right)$.

---

* In obtaining total forces and torques, effect of weight of body must not be neglected.

† Radius of gyration of bob about axis through its mass center parallel to axis of rotation is considered negligible compared with radius of its path.

To determine the motion: $a_t/g = l\alpha/g = -\sin\theta$.

The solution of this equation leads to elliptic functions. An approximate solution for small oscillations can be obtained by putting $\sin\theta = \theta$. (Difference between θ and $\sin\theta$ is less than 1 per cent if θ is less than 14°.) The differential equation becomes $\omega d\omega/d\theta = -g\theta/l$. If the pendulum is at the end of its swing when $t = 0$, then $\theta = \beta$, $\omega = 0$. Integrating, $\omega^2 = g(\beta^2 - \theta^2)/l$; $\omega = \dfrac{d\theta}{dt} = \pm\sqrt{\dfrac{g}{l}(\beta^2 - \theta^2)}$. Integrating, $\theta = \beta\cos\sqrt{\dfrac{g}{l}}\,t$. Period of oscillation $= 2\pi\sqrt{\dfrac{l}{g}}$.

A Conical Pendulum * consists of a small heavy bob suspended from a fixed point by a light string so that it can be made to rotate about the vertical axis through the fixed point (Fig. 10). If the bob rotates with constant angular velocity, ω, the quantities ϕ, r, h are constants. Since there is no vertical acceleration, $T\cos\phi = W$. The force acting inward on the bob is $T\sin\phi$. Hence the force equation gives $T\sin\phi = Wa_n/g = Wv^2/gr$, and $\tan\phi = v^2/gr = r\omega^2/g$. Also $h = g/\omega^2$; $T = Wl\omega^2/g$; period of one revolution $= \dfrac{2\pi}{\omega} = 2\pi\sqrt{\dfrac{h}{g}}$.

A Compound (or Physical) Pendulum is any rigid body suspended from a horizontal axis about which it may rotate under the action of its own weight. The forces acting on the body are its weight, acting downward at G (Fig. 11), and the reaction of the axis at O. Let $\bar{r}$ = distance OG; k = radius of gyration about O. The torque equation gives $Wk^2\alpha/g = -W\bar{r}\sin\theta$, whence $\alpha = -\bar{r}g\sin\theta/k^2$. This is the equation of a simple pendulum (see above) of length $l = k^2/\bar{r}$ called the length of the equivalent simple pendulum. The motion of a compound pendulum is the same as the motion of the equivalent simple pendulum. The point on the compound pendulum located at the distance $k^2/\bar{r}$ from the axis of rotation is called the *center of oscillation.* It coincides with the center of percussion (see above).

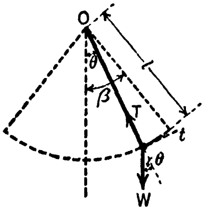

FIG. 9

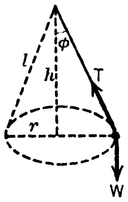

FIG. 10

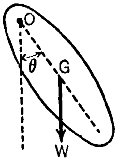

FIG. 11

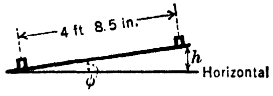

FIG. 12

Super-Elevation of Outer Rail of a Railroad Track is determined as follows (Fig. 12): Let r = radius of curvature in feet and v = speed in feet per second of car. Then horizontal centrifugal force is Wv^2/gr and vertical force is W, acting through mass center.† For the resultant to be perpendicular to the track and thus impose no side load on the rails, $\tan\phi = v^2/gr$. For small angles, the sine instead of the tangent may be used and, if h = super-elevation of the outer rail in inches, $h = 56.5v^2/gr$.

Skidding and Tipping. Suppose a car (Fig. 13) is taking a curve of radius r feet at a speed of v feet per second, G is mass center, N_1 is the vertical and F_1 the horizontal pressure on the outer wheel, and f = coefficient of friction.† The problem becomes one of statics by introducing $Wv^2/gr = F_1 + F_2 = F = fW$. If $f < v^2/gr$, the car will skid. Suppose $f > v^2/gr$; then $N_1 = W(1/2 + v^2h/dgr)$, $N_2 = W(1/2 - v^2h/dgr)$. The critical speed is $v_1 = \sqrt{dgr/2h}$, when the total weight is borne on the outer wheel. If this critical speed is exceeded, the car will tip over.

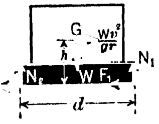

FIG. 13

Note on Use of Rotation Formulas. In practice, nearly all problems of the nature illustrated by the car problems above are solved by the use of formulas applying to rotation of a *particle* about an axis. It should be realized, however, that the assumption thus made that the mass is concentrated at the mass center is not strictly correct except in the event that the body has a true motion of translation (as exemplified by the motion of the parallel rod of a locomotive). Seldom is this the case in practice as usually every line of the body lying in the plane of motion makes one complete revolution for each revolution of the body about the center of rotation of its path. Therefore the formulas applying to rotation of a *body* are the only ones giving absolutely correct results.

For example, in the problem above on the motion of a simple pendulum, considering the path as that of the mass center, the actual torque $T = Wk^2\alpha/g$, where k is radius of gyration of bob about horizontal axis of rotation through O. Let $\bar{k}$ = radius of gyration of bob about horizontal axis through mass center parallel to axis through O. Then $k^2 = l^2 + \bar{k}^2$, and actual torque $T = W(l^2 + \bar{k}^2)\alpha/g$. But the approximate assumption made in the problem that $F_t = Wl\alpha/g$ gives $T = Wl^2\alpha/g$, which is too small by the amount $W\bar{k}^2\alpha/g$. However, when $\bar{k}$ is very small compared with l, the results obtained are sufficiently near accurate.

---

* The principle of the conical pendulum is employed in the Watt governor for steam engines.

† Radius of gyration of the car about axis through its mass center parallel to axis of rotation is considered negligible compared with radius of its path.

21. PLANE MOTION

Kinetic Formulas for plane motion are a combination of those for motions of translation and rotation. The procedure for solution of a problem is summarized in Art. 18 (p. 4–39) under the heading "Plane and Three-Dimensional Motions." The general formula given there for determination of angular accelerations reduces to $T_x = I_x\alpha = mk_x^2\alpha$, the x axis being perpendicular to the plane of motion and passing through the mass center. The theory forming the basis for the assumptions regarding mass concentration and arrangement of forces is explained below under the general case of "Three-Dimensional Motion."

Example: Wheel on Inclined Plane. In Fig. 14, $\tan \beta = 3/4$, the wheel weighs 100 lb, diameter = 4 ft, radius of gyration = 1.6 ft. (*a*) Find the acceleration of the center, if the wheel rolls without slipping. (*b*) Find the least coefficient of friction to prevent slipping. (*c*) If the coefficient of friction = 0.1, find the acceleration of the center and the number of turns made while the center moves 20 ft.

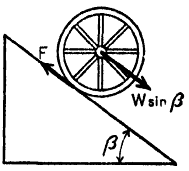

FIG. 14

(*a*) The forces acting to move the wheel are $W \sin \beta = 60$ lb and friction, F. The equation of motion of the center is $100a/32 = 60 - F$. The force acting to turn the wheel is F. The torque equation is $100 \times 1.6 \times 1.6\alpha/32 = 2F$. Since the wheel does not slip, $a = 2\alpha$. Elimination of F and α gives $a = 11.7$ ft per sec².

(*b*) Friction = min. coeff. of friction × normal pressure, or $F = fW \cos \beta$ = minimum $f \times 80$. From the equation above, $F = 23.4$ lb, whence minimum $f = 0.29$.

(*c*) The relation between a and α is not known when the wheel slips. $F = 80 \times 0.1 = 8$ lb. The equation of motion of the center is $100a/32 = 60 - 8 = 52$, whence $a = 16.6$ ft per sec². Distance moved by center, $x = 8.3t^2$. Time to move 20 ft is given by $t^2 = 20/8.3$. Torque equation is $100 \times 1.6 \times 1.6\alpha/32 = 2 \times 8$, whence $\alpha = 2$ rad per sec². The angle turned through, $\theta = t^2 = 20/8.3 = 2.41$ rad = 0.38 revolution.

22. THREE-DIMENSIONAL MOTION

Kinetic Formulas for three-dimensional motion are a combination of those for motions of translation and rotation. The procedure for solution of a problem is summarized in Art. 18 (p. 4–39) under the heading "Plane and Three-Dimensional Motions."

Any motion of a body may be regarded as consisting of two components: one, a translation equal to that of the mass center, and the other a rotation about some axis through the mass center. These motions may be said to be produced independently by the forces acting on the body; thus (*a*) the acceleration of the mass center is the same as if the whole mass were concentrated there and acted upon by forces equal in magnitude to, and the same in direction as, the actual external forces; and (*b*) the angular acceleration is the same as if the mass center were fixed and the actual external forces applied. The reasonableness of this will be seen from the following: imagine each force acting on the body replaced by a force acting at the mass center G and a couple (see p. 4–07); the resultant of all the forces acting at G is a single force R, and the resultant of all the couples is a single couple C; R cannot turn the body but gives it a motion of translation only, and C cannot move G but merely turns the body about some line through G. In general, C does not cause turning about a line perpendicular to the plane of C, only so if the plane of C is perpendicular to one of the principal central axes of the body. To determine the acceleration of the mass center, take fixed x, y, and z axes outside the body and resolve all external forces F_1, F_2, etc., into x, y, and z components; then

$$\Sigma F_x = m\bar{a}_x \qquad \Sigma F_y = m\bar{a}_y \qquad \Sigma F_z = m\bar{a}_z$$

m denoting the mass of the body. To determine the angular acceleration of the body, take moments of all the forces F_1, F_2, etc., about the three central principal axes; calling the sums of the moments about these axes ΣT_1, ΣT_2, and ΣT_3, the components of the angular acceleration α_1, α_2, and α_3, and the components of the angular velocity ω_1, ω_2, and ω_3, then

$$\Sigma T_1 = I_1\alpha_1 + (I_3 - I_2)\omega_2\omega_3;\ \Sigma T_2 = I_2\alpha_2 + (I_1 - I_3)\omega_3\omega_1;\ \Sigma T_3 = I_3\alpha_3 + (I_2 - I_1)\omega_1\omega_2$$

wherein I_1, I_2, and I_3 denote the three central principal moments of inertia of the body. In any motion of a body, the kinetic energy may be computed in two parts: (1) the kinetic energy of the whole body moving with a velocity equal to that of the mass center, and (2) the sum of the kinetic energies of the constituent particles of the body due to their velocities relative to an axis through the mass center.

23. FRICTION

Static and Kinetic Friction

A Smooth Surface is one which offers no resistance to the sliding of a body upon it. **A rough surface** does offer resistance to such motion. **The total reaction** (R) (Fig. 15) of the surface of one body upon another body is its resultant force. *Friction* (F) is that component of the total reaction which is tangent to the surface. *Normal reaction* (N) is that component which is normal to the surface.

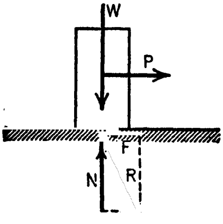

Fig. 15

Static Friction (F) is that friction which opposes motion when there is no slipping. Its value varies as the need for it to prevent motion is developed. *Limiting friction* (F') is the value of static friction when slipping impends. *Coefficient of static friction* (f) is the ratio F'/N. *Angle of static friction* (ϕ) is defined by $\tan \phi = F'/N = f$. *Angle of repose* is that angle which the surface of one body makes with the horizontal when slipping of another body upon it impends. It applies to the particular rubbing surfaces in contact. It equals the angle of static friction.

Kinetic Friction (F_k) is that friction which opposes motion when one body is slipping on the surface of the other. Its value is usually less than that of the limiting friction. *Coefficient of kinetic friction* (f_k) is the ratio F_k/N. *Angle of kinetic friction* (ϕ_k) is defined by $\tan \phi_k = F_k/N = f_k$.

Laws of Friction for Dry Surfaces:

1. Friction between two given bodies is directly proportional to the pressure; the coefficient of friction is constant for all pressures.
2. The coefficient and amount of friction for given pressures are independent of the area of contact.
3. The coefficient of friction is independent of the relative velocity, although static friction is greater than kinetic friction.

The preceding laws are only approximately true. The coefficient of friction is slightly greater for small pressures upon large areas than for great pressures upon small areas. The coefficient of friction decreases as the speed increases.*

Laws of Friction for Lubricated Surfaces:

The friction does not follow the laws for dry surfaces, but depends on the viscosity and thickness of the lubricant and the form of the surfaces in contact. The laws given by Goodman are:

1. The coefficient of friction of well-lubricated surfaces is from $1/16$ to $1/10$ that of dry or poorly lubricated surfaces.
2. The coefficient of friction for moderate pressures and speeds varies approximately inversely as the normal pressure; frictional resistance varies as the area of contact, normal pressure remaining the same.
3. For low speeds the coefficient of friction is abnormally high, but as the speed of the rubbing surfaces increases from about 10 to 100 ft per min, the coefficient of friction diminishes and again rises when that speed is exceeded, varying approximately as the square root of the speed.
4. The coefficient of friction varies approximately inversely as the temperature.

Coefficients of Static and Kinetic Friction are affected by the above laws of friction and also by the characters of the surfaces, the kinds of material, and the nature of any lubricant used. Rough averages for a number of materials and conditions are given in Table I, p. 4–45.†

Rolling Friction

Rolling Friction is that friction developed when one body rolls over the surface of another, and depends on the hardness of the surfaces in contact and the radius of the rolling surface. The theory is based on the idea that surfaces are slightly deformed at the place of contact and that the effect of rolling friction is the same as if the surfaces were not deformed and the rolling body passed constantly over a small obstruction. Let P (Fig. 16) be the horizontal force required to overcome the small obstruction B. Then $hP = aW$, and, since h is nearly equal to r, $P = aW/r$ (approximately). *Coefficient of rolling friction* is a, and, as an analogy with definitions of static and kinetic friction coefficients, might be defined as the ratio T_r/N, where T_r = torque resisting rolling motion and N is the normal force (in this case,

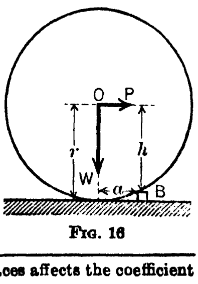

Fig. 16

---

* Recent experiments have proved also that time of contact of the surfaces affects the coefficient of static friction.

† Hudson's Manual, p. 102.

the weight of the body). The coefficient is a linear distance and is usually given in inches.

Coefficients of Rolling Friction. The following are some reported values of coefficients of rolling friction:

Lignum vitae roller on oak track	0.019 in.
Elm roller on oak track	0.032 in.
Cast-iron wheel (20-in. diam.) on cast-iron rail	0.018–0.019 in.
Railroad wheels (39.4-in. diam.)	0.020–0.022 in.
Iron or steel wheels on wood track	0.06–0.10 in.

Table I. Coefficients of Static and Kinetic Friction

Axle Friction

Axle Friction is that friction which opposes the turning of an axle in its bearing. Its value depends on (*a*) the method of lubrication, (*b*) the lubricant, (*c*) its temperature, (*d*) the velocity of rubbing, and (*e*) the intensity of pressure on the bearing.

If a cylindrical axle fits loosely in a cylindrical bearing, the bearing surface will be a narrow strip or element. If the axle turns in the direction of the arrow (Fig. 17), it will rise in the bearing to some position as shown. F is friction, N normal pressure, and $R = \sqrt{F^2 + N^2}$ = resultant pressure of bearing on axle. *Coefficient of friction* (f) is the ratio F/N. *Angle of friction* (ϕ) is defined by $\tan \phi = F/N = f$. Since N and R are practically equal, we may put $N = R$, giving $F = fR$. Then the torque exerted by the bearing during each revolution of the shaft = rfR pound-inches where r = radius of shaft in inches. The power necessary to overcome friction when the axle makes n revolutions per second is $P = \pi nrfR/6$ foot-pounds per second.

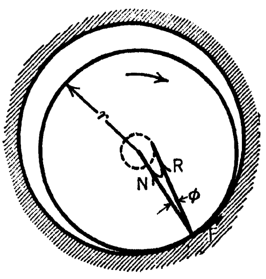

FIG. 17

Pivot Friction

Pivot Friction is that friction which opposes the turning of the end of a vertical, or inclined, shaft in its bearing. Some examples of pivot friction, with friction torque and power formulas applying, are shown in the following table:

Table II. Pivot Friction *

f = coefficient of friction. W = load in pounds.
T = torque of friction about the axis of the shaft.
r = radius in inches. n = revolutions per second.

Type of Pivot	Torque T in Pound-inches	Power P Lost by Friction in Foot-pounds per Second
Shafts and Journals  (180° bearing)	$T = fWr$	$P = \frac{2\pi n}{12} fWr.$
Flat Pivot  	$T = {}^2/_3\, fWr.$	$P = \frac{4\pi n}{3 \times 12} fWr$
Collar-bearing  	$T = {}^2/_3\, fW \frac{R^3 - r^3}{R^2 - r^2}$	$P = \frac{4\pi n}{3 \times 12} fW \frac{R^3 - r^3}{R^2 - r^2}$
Conical Pivot  	$T = {}^2/_3\, fW \frac{r}{\sin \alpha}$	$P = \frac{4\pi n\, fWr}{3 \times 12 \sin \alpha}$
Truncated-cone Pivot  	$T = {}^2/_3\, fW \frac{R^3 - r^3}{(R^2 - r^2) \sin \alpha}$	$P = \frac{4\pi n\, fW(R^3 - r^3)}{3 \times 12(R^2 - r^2) \sin \alpha}$

---

* Hudson's Manual, p. 105.

Belt or Coil Friction

Belt or Coil Friction is that friction which opposes the slipping of a belt, rope, brake band, or similar article coiled about a pulley, sheave, post, capstan, or similar device. When power is being transmitted, say by a belt driving a pulley, the tension T_1 on the driving side of the belt is greater than the tension T_2 on the driven side. Neglecting the effect of centrifugal force, which is small at low speeds, the tensions are related by the formula $T_1/T_2 = e^{f\alpha}$ where $e = 2.718 +$ (i.e., base of natural logarithms), f = coefficient of friction between belt and pulley, and α = angle of contact between belt and pulley (Fig. 18). Values of T_1/T_2 for various values of f and α are shown in the table below.

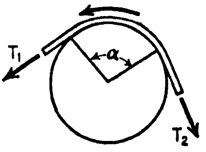

Fig. 18

Table III. Maximum Ratio T_1/T_2 (Slipping Impending)

α Radians	Values of f (Coefficient of Friction)

MECHANICS OF MATERIALS

SIMPLE STRESSES

By Jasper O. Draffin

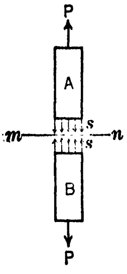
1. TENSION, COMPRESSION, SHEAR

Stress or Total Stress is the resultant internal force that resists change in the size or shape of a body acted on by external forces. A change in size or shape begins when the load is applied and stops when the internal resisting stress holds the external forces in equilibrium. If the external forces acting on the body increase to the extent that the maximum stress that can be developed is unable to balance the external forces, the change in form will increase rapidly and the body will break or rupture. Stresses are measured in the same units as the forces which produce them, i.e., pounds, tons, etc.

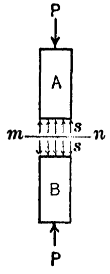
Unit Stress or intensity of stress is defined as the stress per unit of area. Its value at any point of a section is the stress on an elementary part of the area, including the point, divided by the elementary area, and generally varies from point to point of the section. When the stress (P) is uniformly distributed over an area (A), the unit stress (s) at any point of the area is the stress on the area divided by the whole area; i.e., $s = P/A$. Unit stresses are expressed in pounds per square inch, tons per square foot, kilograms per square centimeter, and the like.

Both total stress and unit stress are often referred to simply as "stress." Confusion will be avoided if the units used are stated.

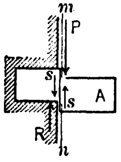
Tensile Stress or Tension is the internal force that resists the action of external forces tending to increase the length of a body. Tension is developed in a bar when the external forces act on it in the directions away from its ends. See Fig. 1. The tendency is to separate the bar into two parts, A and B. To maintain equilibrium each part is acted on at section mn by tensile stresses, s, whose resultant is equal and opposite in direction to the resultant of the external forces acting at the end of the part considered. If the forces acting on one end of the bar total 1000 lb then the stress on the section mn equals 1000 lb.



Tension
FIG. 1



Compression
FIG. 2



Shear
FIG. 3

Compressive Stress or Compression is the internal force that resists the action of external forces tending to decrease the length of a body. Compression is developed in a bar when external forces act on it in the directions toward its ends. In Fig. 2, the tendency of the external forces is to shorten the bar by pushing any two parts, as A and B, closer together. As long as equilibrium is maintained, the resultant of the compressive stresses acting on either part at section mn is equal and opposite in direction to the resultant of the external forces acting at the end of the part considered.

Shearing Stress or Shear is the internal force acting along a plane between adjacent parts of a body when two equal forces parallel to the plane considered act on each part in opposite directions. The shear resists the tendency of one part to slide over the other part. In Fig. 3, the projecting part of the cantilever beam, A, is acted on by external vertical forces due to the weight of A and any loads that it carries. The resultant of these forces, P, is equal, parallel to, and opposite in general direction to the upward pressure or reaction, R, which acts on the part of the beam embedded in the wall. There exists, therefore, a tendency of the parts to assume the relative positions shown in Fig. 3. An internal force acting along the cross-section mn resists the tendency of A to slide vertically downward. This internal force is the shear acting on the cross-section. As long as equilibrium is maintained, if P equals 1000 lb, R also equals 1000 lb, and the shear acting on the section equals 1000 lb.

Simple Stress. Tension, compression, and shear are considered singly and in combination in engineering practice. When it is necessary to consider only one of these singly, the case is known as one of simple stress.

Normal Stress. A normal stress on a section is one that acts in a direction perpendicular to the section considered.

Axial Stress. Axial tension or compression exists in a straight homogeneous bar when the resultant of the applied loads coincides with the axis of the bar. The stress then is distributed uniformly over any section normal to the axis of the bar.

Axial tension is encountered in a vertical bar supported only at its upper end; the tension caused by the weight of the bar and any load carried at its lower end is uniformly distributed over the cross-section of the bar. If the resultant of the applied load does not coincide with the axis of the bar, the stress is not uniform over the cross-section of the bar. For a bar held in an inclined position, even though subjected to axial force applied at its ends, the weight of the bar itself is an external force acting on it at an angle to its axis. Therefore, this is not simple axial tension, and the stress is not uniform over a cross-section of the bar.

Axial compression exists in a pier or prism of length not exceeding 6 to 8 times the least side or diameter, when the resultant of the load supported acts through the centers of gravity of the end sections. When the length is greater than 6 or 8 times the least side or diameter, the pier is regarded as a column in which some bending has taken place. Then the resultant of the load, though acting through the centers of gravity of the end sections, does not coincide with the axis of the column; the stresses therefore are not uniformly distributed over a cross-section and the case is not one of simple axial compression.

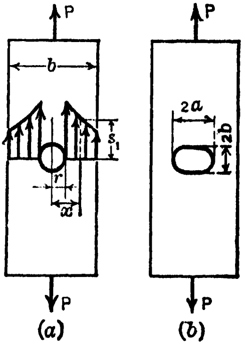


FIG. 4

Effect of Notches and Holes in Members under Simple Stress. In the formula $s = P/A$, it is assumed that the stress is uniformly distributed over the cross-section of the member. But this is not true if there is any discontinuity in the cross-section, as an increase or decrease in area. In Fig. 4(a), a plate of width b, having a small hole of radius r, is subjected to an axial pull, P. The unit stress s_1, at any distance x from the center line, is given by the formula (Timoshenko and Lessells, Applied Elasticity, p. 9),

$$s_1 = \frac{s}{2}\left(2 + \frac{r^2}{x^2} + 3\frac{r^4}{x^4}\right) \tag{1}$$

where s is the unit stress, based on the load P and the area, using the full width b. Where the radius r does not exceed $b/12$, the stress $s_1 = 3s$.

For an elliptical hole of major axis $2a$ and minor axis $2b$, Fig. 4(b), the maximum unit stress is $s_1 = s(1 + 2a/b)$. Notches of small radius on opposite sides of a tension specimen produce stresses approximately twice as great as the average stress; an example of this is the common briquette used in testing cement, in which the maximum tensile unit stress at the sides is 1.75 times the average stress (Coker, *Proc.* Inter. Soc. Test. Mat., 1913).

2. DEFORMATION UNDER STRESS

Deformation is the amount of the change in the shape of a body caused by the application of external forces. When the external forces cause tension the deformation is the amount that the body is increased in length; when they cause compression, it is the amount that the body is decreased in length; when they cause shear, it is the amount that one part of the body slips over the adjacent part. The deformations accompanying tension, compression, and shear are known, respectively, as elongation, shortening, and detrusion. Deformations are measured by the same units of length used in measuring the linear dimensions of the body.

Unit Deformation, or deformation per unit of length, is determined by dividing the total amount of deformation by the original length of the body before the load causing the deformation was applied. If a steel bar 8 in. long is stretched until it becomes 8.16 in. long the total deformation, in this case elongation, is 0.16 in.; the unit deformation, ϵ, is 0.16 ÷ 8 = 0.02 in. per in. of original length.

The ultimate unit deformation is the unit deformation measured after the body has ruptured; it is usually expressed as a percentage of original length. Thus, if two marks on a bar of hard steel are 2 in. apart before a test and 2.30 in. apart after rupture, the ultimate unit deformation, ϵ, is the difference between these distances divided by the original distance between the two marks: or $\epsilon = 0.30 \div 2.0 = 0.15$ in. per in. = 15 per cent.

Hooke's Law. It has been found by experiment that a body acted on by external forces will deform in proportion to the stress developed as long as the unit stress does not exceed a certain value, which varies for the different materials. This value is the *proportional limit.*

Stress and Strain. The word strain has been frequently used for the internal force in a body, or stress. It is present practice, however, to use the word strain as a synonym for deformation only. Thus the expression "stress and strain" is equivalent to the expression "stress and deformation." Owing to the conflicting meanings of the word strain it has been suggested that it be avoided, the word deformation being used in its place. Physicists usually define strain as the deformation per unit length.

The Proportional Limit is that unit stress at which the unit deformation begins to increase at a faster rate than does the unit stress, or it is the highest unit stress at which the stress is proportional to the deformation. It is determined by noting, on a stress-deformation diagram, the unit stress at which the curve departs from a straight line.

The Elastic Limit is the maximum unit stress to which a material may be subjected and still be able to return to its original form upon the removal of the stress. When stressed beyond the elastic limit a body will return to its original form only partially and thereby acquires a permanent deformation or "set." The determination of the elastic limit logically involves the application and release of a series of increasing loads on the specimen until a set is observed after the release of a load. This procedure is very slow; and, since for many metals experience does not indicate any significant difference between the elastic limit so determined and the proportional limit, the proportional limit is often accepted as equivalent to the elastic limit, and is frequently called the *proportional-elastic limit.* It should be remembered, however, that there is no fundamental relationship between the elastic limit and the proportional limit. In many of the older tests, particularly with timber, the proportional limit was incorrectly reported as the elastic limit.

Johnson's Apparent Elastic Limit. For some materials it is difficult to determine precisely the proportional limit since the point of departure of the stress-deformation curve from a straight line is not well defined. In view of this, J. B. Johnson proposed what he called the "apparent elastic limit" as the point on the stress-deformation diagram at which the rate of deformation is 50 per cent greater than at the origin. It is found by drawing a line, OA, Fig. 5, having a slope with respect to the vertical axis 50 per cent greater than the straight-line part of the curve; the unit stress at which this line is tangent to the curve, point B on the line $O'A'$, Fig. 5, is the apparent elastic limit.

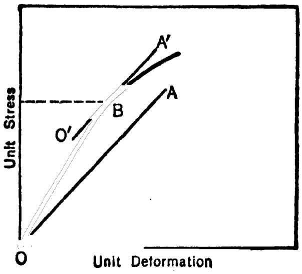

FIG. 5

The Yield Point of a material is the unit stress at which the deformation first increases markedly without any increase in the applied load. The yield point is always above the proportional limit and true elastic limit. Ductile metals have a well-defined yield point which is practically the same value as the proportional limit. For this reason, and because of the method of commercial testing, the yield point of ductile metals is sometimes reported as the elastic limit, or as the *commercial elastic limit.* The A.S.T.M. Standards, 1933, E8-33, specify that the term, yield point, shall not be used in connection with material whose stress-deformation curve in the region of yield is a smooth curve of gradual curvature.

Yield Strength is defined as the unit stress at which a material exhibits a specified limiting permanent set. It is a measure of the useful limit of materials, particularly of those whose stress-deformation curve in the region of yield is a smooth curve of gradual curvature. For methods of determining yield strength, see p. 5-87.

The Ultimate Strength, tensile or compressive strength, of a material is the highest unit stress it can sustain before rupturing.

The Point of Rupture, or breaking strength, is the unit stress at which the material tested breaks or ruptures. It is observed in tests on steel to be slightly less than the

ultimate strength or maximum stress sustained before rupture because of the large reduction in area before rupture.

Stress-deformation Diagram. The relation between the unit stress and unit deformation for any material tested is shown conveniently by a stress-deformation diagram, in which ordinates to a curve represent unit stresses and abscissas the resulting unit deformations for all values of unit stress to the point of rupture. In a typical tension test on a bar of medium steel, the curve, Fig. 6, is a straight line up to a unit stress of about 35,000 lb per sq in., showing a constant ratio of unit stress to unit deformation. The proportional limit, point *a*, is the unit stress at which the curve deviates from the initial straight line.

At a unit stress slightly higher than the proportional limit, point *b*, the curve becomes approximately horizontal, showing a rapid increase in deformation without any further increase in the stress; this unit stress is the yield point. For unit stresses beyond the yield point, the curve shows that the rate of deformation increases rapidly. The end of the curve, beyond point *c*, marks the point of rupture which is shown to be a little lower than the maximum unit stress (ultimate strength) sustained during the test.

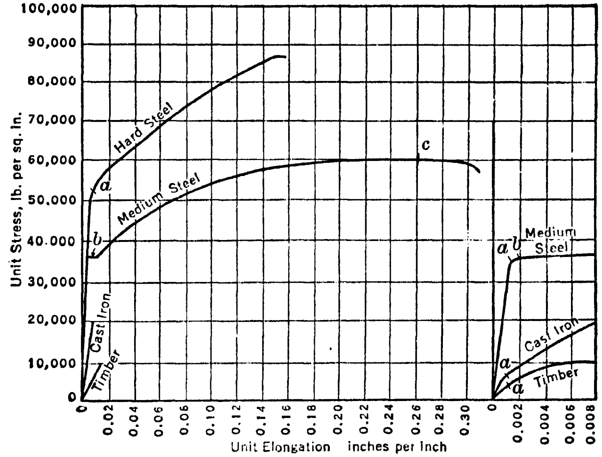

FIG. 6. Stress-Deformation Diagram

The form of the curve obtained from a test will vary according to the material tested, and will be different for compression than for tension. For some materials, like cast iron, concrete, and frequently, timber, no part of the curve is a straight line.

Modulus of Elasticity in tension or compression is the constant which expresses the ratio of unit stress to unit deformation for all values of unit stress not exceeding the proportional limit of a material. The terms *coefficient of elasticity* and *Young's modulus* are sometimes used to express this ratio.

The deformation caused by any unit stress not exceeding the proportional limit may be computed if the modulus of elasticity is known. Consider a bar of length l and cross-sectional area A acted on by an axial load P which produces a total deformation e. The unit stress is P/A, and the unit deformation is e/l. Let E represent the modulus of elasticity, s the unit stress, and ϵ the unit deformation, then

$$E = \frac{\text{Unit stress}}{\text{Unit deformation}} = \frac{s}{\epsilon} = \frac{P/A}{e/l} = \frac{Pl}{Ae} \tag{2}$$

or

$$e = \frac{Pl}{AE} = s\frac{l}{E} \tag{3}$$

Since l and e are linear dimensions, ϵ is an abstract number, and E is expressed in the same units as s, such as pounds per square inch, tons per square foot, or kilograms per square centimeter.

This formula can be used only for unit stresses not greater than the proportional limit because for higher unit stresses the ratio s/ϵ is not constant. The modulus of elasticity, E, is a measure of the stiffness of a body or its ability to resist deformation within the proportional limit of the material. The greater the modulus of elasticity the less will be the deformation for any unit stress not exceeding the proportional limit.

For any given material, the modulus of elasticity is often the same in tension or compression. Average values for steel, and wrought iron are respectively 30,000,000 lb per sq in. and 25,000,000 lb per sq in. Values for other materials are given in Table 23 Section 1, and Sections 11 and 12. Axial stresses are always implied when the unqualified term "modulus of elasticity" is used.

Modulus of Elasticity in Shear. The expression for the modulus of elasticity in shear is similar to that for tension or compression; but in shear the deformation is in a direction lying in the plane of shear of the body. The modulus of elasticity in shear is sometimes called the *modulus of rigidity.*

Let E_s be the shearing modulus of elasticity, s_s the unit shearing stress, e_s the total lateral deformation or detrusion due to the shear, and ϵ_s the unit detrusion, then

$$E_s = \frac{\text{Unit shearing stress}}{\text{Unit detrusion}} = \frac{s_s}{\epsilon_s} = \frac{P/A}{e_s/l} = \frac{Pl}{e_s A} \qquad (4)$$

or

$$e_s = \frac{Pl}{AE_s} = \frac{s_s l}{E_s} \qquad (5)$$

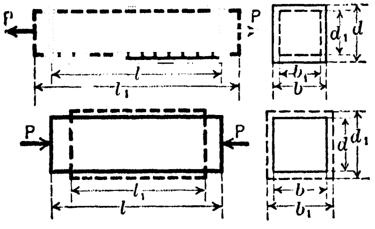

FIG. 7

For metals, the shearing modulus of elasticity is approximately 0.4 times the tensile modulus of elasticity.

Poisson's Ratio. The elongation or shortening of a bar under axial stress is accompanied by a reduction of the cross-sectional area in tension and an increase in the cross-sectional area in compression. The two cases are illustrated in Fig. 7. It has been established by experiment that the lateral unit deformation or change per unit diameter or other lateral dimension is proportional to the linear unit elongation or shortening. The ratio of lateral unit deformation to linear unit deformation within the elastic limit is known as *Poisson's ratio* or the "factor of lateral contraction." Average values for the common materials of construction are as follows:

Material..........	Steel	Wrought Iron	Cast Iron	Brass	Concrete
Poisson's ratio.....	0.333	0.333	0.25	0.333	0.10

Denoting Poisson's ratio by λ, and the length and diameter of the bar, after stress has been acting, by l_1 and d_1, respectively, then

$$\text{For tension............} \quad l_1 = (1 + \epsilon)l; \quad d_1 = (1 - \lambda\epsilon)d \qquad (6)$$

$$\text{For compression........} \quad l_1 = (1 - \epsilon)l; \quad d_1 = (1 + \lambda\epsilon)d \qquad (7)$$

in which l and d are the original length and diameter and ϵ the longitudinal unit elongation or shortening as the case may be.

3. PHYSICAL PROPERTIES OF MATERIALS OBSERVED IN TESTS

Elasticity. A material is elastic when it is able to deform and return to its original shape upon the removal of the load. Regardless of the amount of deformation, the ability to recover its original form is the criterion of elasticity. Steel is elastic within its elastic limit; but for higher unit stresses, causing greater deformations, much of its elasticity is lost, as the material only partially returns to its original form when the stress is removed.

Ductility and Malleability are often used synonymously to indicate the ability of a material to undergo large permanent deformations without rupture. Ductility is commonly thought of as the property which enables a material to be drawn into a wire, whereas malleability is the property which permits it to be beaten or rolled into thin sheets. Ductility is frequently more specifically defined as the ability to undergo large permanent deformations in tension, and malleability, the ability to undergo large permanent deformations in compression.

Plasticity. A material is plastic if the smallest load produces a permanent deformation. A perfectly plastic material is non-elastic and has no ultimate strength in the ordinary meaning of the term. Lead is an example of a plastic material, for a prism tested in compression will deform permanently under a small load and will continue to deform as the load is increased until it flattens out into a thin sheet. Wrought iron and soft steel become plastic when stressed beyond the elastic limit in compression, their behavior resembling that of lead; when stressed beyond the elastic limit in tension they are partly elastic and partly plastic, the degree of plasticity increasing as the ultimate strength is approached.

Brittleness. A material which can be only slightly deformed without rupture is termed brittle. Brittleness is relative, no material being perfectly brittle, that is, capable of no deformation before rupture. Many materials are brittle to a greater or less degree, glass being one of the most brittle of materials. Brittle materials have relatively short stress-deformation curves, since they are capable of only small deformations before rupture. Of the common structural materials, cast iron, brick, and stone are to be considered brittle in comparison with steel.

Brittleness and Plasticity are opposite terms. Materials which have a high degree of plasticity have no brittleness, and they rupture with considerable reduction of area. The reduction of area at rupture may be considered the measure of the plasticity or brittleness of a material, a large reduction of area indicating a high degree of plasticity and little or no reduction of area indicating a high degree of brittleness.

Toughness is the ability to withstand high unit stress together with great unit deformation, without complete fracture. The area under the curve of the stress-deformation diagram, area *OAGH*, or *OJK*, Fig. 8, is a measure of the toughness of the material. The distinction between ductility and toughness is that ductility deals only with the ability to deform, whereas toughness considers both the ability to deform and the stress developed during deformation.

Stiffness is the ability to resist deformation under stress. The modulus of elasticity is the criterion of the stiffness of a material.

Hardness is the ability to resist very small indentations, abrasion, and plastic deformation. There is no single measure of hardness, as it is not a single property but is a combination of several properties.

Creep or Flow of Metals. This is a phase of plastic or inelastic action. Some solids, as asphalt or paraffin, flow appreciably at room temperatures under extremely small stresses; while zinc, lead, and tin show signs of creep at room temperature under moderate stresses. At sufficiently high temperatures, practically all known metals creep under stresses which vary with the temperature, the higher the temperature the lower the stress at which creep takes place. This deformation due to creep continues to increase indefinitely and becomes of extreme importance in members subjected to high temperatures, as parts in turbines, boilers, superheaters, etc. Considerable work has been done on this phase of the strength of materials since about 1919, and many data have been accumulated, but the field has only begun to be explored.

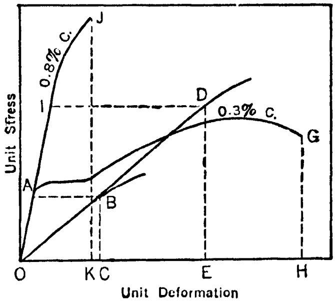

FIG. 8

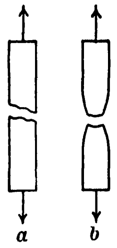

FIG. 9

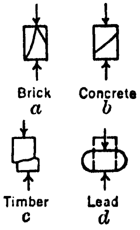

FIG. 10

Creep Limit is the maximum unit stress under which the unit distortion will not exceed a specified value during a given period of time at a specified temperature. A value which has been much used in tests and which has been suggested as a standard for comparing materials is the maximum unit stress at which the creep does not exceed 1 per cent in 100,000 hours.

Types of Fracture. The materials of engineering have varying degrees of elasticity, ductility, plasticity, and brittleness, which properties are partly indicated by the method in which a test specimen breaks. A bar of brittle material, as cast iron, will rupture in a tension test, as shown in Fig. 9*a*, in a clean, sharp fracture with very little reduction of cross-sectional area and very little elongation; in a ductile material such as structural steel, the reduction of area and elongation are greater, as shown in Fig. 9*b*. In compression, a prism of brittle material will break by shearing along oblique planes and the greater the brittleness of the material the more nearly these planes will parallel the direction of the applied force. Figs. 10*a*, 10*b*, and 10*c*, arranged in order of brittleness, illustrate the type of fracture in prisms of brick, concrete, and timber. Fig. 10*d* represents

the deformation of a prism of plastic material, as lead, which flattens out under load without failure.

4. WORK AND RESILIENCE

External Work. If an axial load on a bar is increased gradually from zero to its final value, P pounds, causing an internal stress not greater than the proportional limit, the mean force acting is $\frac{1}{2}P$ and the distance through which it acts is the deformation, e, inches. Let W be the external work performed on the bar, inch-pounds; then $W = \frac{1}{2}Pe$. If s = the unit stress, pounds per square inch, caused by P, A = the sectional area in square inches, l = the length in inches, and E = the modulus of elasticity in pounds per square inch, then $P = As$, and for all values of s within the proportional limit, $e = sl/E$. Substituting these values in the above expression, the work required to produce deformation in terms of s, A, and l within the proportional limit may be expressed as follows:

$$W = \frac{1}{2}As\left(\frac{sl}{E}\right) = \frac{1}{2}\left(\frac{s^2}{E}\right)Al \qquad (8)$$

The factor $\frac{1}{2}s^2/E$ is the work required per unit volume, the volume being Al; it is represented on the stress-deformation diagram by the area of the triangle formed by the stress-deformation curve, the ordinate representing the unit stress considered, and the axis of deformations, area ODE or OBC, Fig. 8, p. 5–07.

Resilience is a term denoting stress energy which may be recovered from a deformed body when the load causing the stress is removed. Within the proportional limit, the resilience is equal to the external work performed in deforming the bar; therefore the resilience is equal to $\frac{1}{2}(s^2/E) \times Al$. When s is equal to the proportional limit the factor $\frac{1}{2}s^2/E$ is known as the *modulus of resilience*, it being the measure of the capacity of a unit volume of the material to store stress energy up to the proportional limit. Average values of the modulus of resilience under tensile stress, in inch-pounds per cubic inch, for various materials are given in Table I.

The total resilience of a bar is the product of its volume and the modulus of resilience. The above formulas for work performed on a bar and its resilience do not apply if the unit stress is greater than the proportional limit.

Table I. Average Values of Tensile Modulus of Resilience and Toughness

(Inch-pounds per cubic inch)

Material	Modulus of resilience	Relative toughness (area under curve of stress-deformation diagram)
Gray cast iron	1.2	70
Malleable cast iron	17.4	3800
Wrought iron	11.6	11000
Low-carbon steel	15.0	15700
Medium-carbon steel	34.0	16300
High-carbon steel	94.0	5000
Ni-Cr steel, hot-rolled	94.0	44000
Vanadium steel, 0.98% C, 0.2% V, heat-treated	260.0	22000
Duralumin, 17 ST	45.0	10000
Rolled bronze	57.0	15500
Rolled brass	40.0	10000
Oak	2.3*	13*

* Bending.

Work Required for Rupture. Since beyond the proportional limit the deformations are not proportional to the stresses, $\frac{1}{2}P$ does not express the mean value of the force acting. The formula $W = \frac{1}{2}(s^2/E)Al$ therefore does not express the work required for deformations after the proportional limit of the material has been passed, and cannot express the work required for rupture. The work per unit volume required to produce deformations beyond the proportional limit or for rupture may, however, be determined from the stress-deformation diagram, as it is measured by the area included between the axis of abscissas, and the stress-deformation curve up to the deformation in question, as $OAGH$ or OJK, Fig. 8, p. 5–07. This area, however, does not represent the resilience, since part of the work done on the bar is present in the form of heat and cannot be recovered. The total work required for rupture, area $OAGH$, is taken as a measure of the toughness of the material. See p. 5–07.

5. COMBINED ELEMENTARY STRESSES

Shear Due to an Axial Stress. When an axial load acts on a bar it causes normal stress on the cross-sections and both normal and shearing stress on sections inclined to the axis. Thus in Fig. 11 the axial load P may be resolved into components P_1 and P_2 acting parallel and normal to any inclined plane as *mn*. P_1 causes shear and P_2 causes normal stress on the oblique section. When the section *mn* makes an angle of 0° or 90° with the axis, the shearing stress will be zero. When the section *mn* makes an angle of 45° with the axis of the bar, the unit shearing stress due to axial load (tensile or compressive) is at a maximum and is

$$s_{s_{\max}} = \frac{1}{2}\frac{P}{A}$$

where A is the cross-sectional area of the bar.

Shear Due to Normal Stresses at Right Angles. When two forces act on a body in directions at right angles to each other, causing unit stresses s_1 and s_2 (tensile stress considered positive and compressive stress negative) on planes normal to the direction of the applied forces, the maximum unit shearing stress is $s_{s_{\max}} = {}^1\!/_2(s_1 - s_2)$ and acts along each of the two planes that make an angle of 45° with the planes normal to the direction of the applied forces.

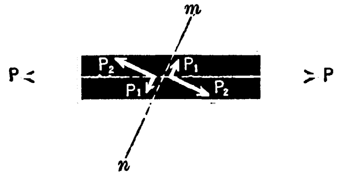

FIG. 11

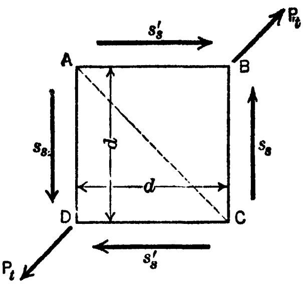

FIG. 12

Tensile or Compressive Stress Due to Shear. In a body subjected to shear (e.g., a bar in torsion), a particle of unit dimensions shown enlarged in Fig. 12 has acting upon it the couple $s_s d$, and balancing it, the couple $s_s' d$. For equilibrium the two couples must be equal, hence $s_s = s_s'$. These stresses will result in a maximum tensile force normal to the plane through AC and perpendicular to the paper, $P_t = \sqrt{2s_s^2}$, and a maximum unit tensile stress normal to this plane, $s_t = \dfrac{\sqrt{2s_s^2}}{\sqrt{2}} = s_s$. Similarly, normal to the plane through BD and perpendicular to the paper, there is a maximum unit compressive stress $s_c = s_s$. These stresses are particularly important in brittle materials which, when subjected to torsion, usually fail in tension with a helical fracture.

Combined Axial Stresses. Assuming tensile stresses to be positive and compressive stresses negative, the normal stress on a section due to several applied axial loads is equal to the algebraic sum of the normal stresses caused by each load. Thus if a bar is subjected to applied axial loads P_1, P_2, P_3, and P_4 causing unit stresses on the cross-section of the bar equal to $-20{,}000$, $+12{,}500$, -6000, and $+8000$ lb per sq in., respectively, the normal axial unit stress is -5500 lb per sq in., the negative sign indicating that the combined stress is compressive.

Deformation Due to Normal Stresses at Right Angles. Let s_1 and s_2 be the unit tensile stresses in each of the two directions on the element of plate in Fig. 13, the direction of each stress being normal to the plane on which it acts. The stress s_1 will produce a unit elongation $\epsilon_1 = s_1/E$ in the direction of s_1, and at the same time, a unit lateral contraction of $\lambda\epsilon_1$ in the direction of s_2 where λ represents Poisson's ratio. Similarly the unit stress s_2 will produce a unit elongation of $\epsilon_2 = s_2/E$ in the direction of s_2 and a lateral contraction of $\lambda\epsilon_2$ in the direction of s_1. The resultant unit elongation in the direction of s_1 will then be $\epsilon_1 - \lambda\epsilon_2$, and in the direction of s_2 it will be $\epsilon_2 - \lambda\epsilon_1$. If the stress s_2 were compression and the stress s_1 tension, the resultant elongation in the direction of s_1 would be $\epsilon_1 + \lambda\epsilon_2$, and the resultant contraction in the direction of s_2 would be $\epsilon_2 + \lambda\epsilon_1$.

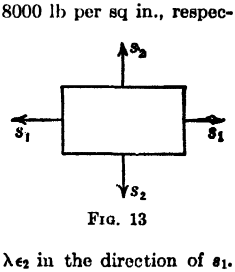

FIG. 13

The effect then of two normal stresses acting at right angles to each other on a plate is to reduce the resultant deformation if both stresses are alike, and to increase the resultant deformation if the stresses are unlike. By experiment, $s = \epsilon E$, and for a uniaxial stress this accords with the definition that $s = P/A$; but if the resultant unit deformation due to biaxial loading is multiplied by E, the modulus of elasticity, the resulting unit stress in the direction of either applied load will not be the same as that obtained by $s = P/A$. Thus the question is involved whether the liability of the member to fail is measured by the stress based on the external loads or by the deformation of the material. There is a lack of complete agreement as to which criterion should be used, but if both stresses are tension or compression, it is on the side of safety to neglect the effect of the lateral stresses and to use the stress based on the external loads, or $s = P/A$. If the lateral stresses are of opposite sign from the longitudinal stresses, and increase the longitudinal deformation, the effect of the increased deformation may need to be considered. See Seely, Resistance of Materials, 2nd Ed. (John Wiley & Sons, New York), pp. 234–239.

Combined Tension or Compression and Shear. If a particle is subjected to tensile or compressive as well as shearing stresses there will be a plane in the particle normal to which the unit tensile or compressive stress will be a maximum, and two planes, each at an angle of 45° to the one on which the maximum unit tensile or compressive stresses occur, on which the unit shearing stress will be a maximum. In Fig. 14, the particle is subjected to a unit shearing stress of s_s and a unit tensile stress of s_t. Then (Seely's Resistance of Materials or Boyd's Strength of Materials),

$$s_{t\max} = (s_t/2) + \sqrt{s_s^2 + (s_t/2)^2}, \tag{9a}$$

and the plane m–n to which it is normal is at an angle θ_t with the direction of s_t such that $\tan 2\theta_t = -2s_s/s_t$. With the same combination of stresses the maximum unit compressive or minimum unit tensile stress, at 90° to the maximum unit tensile stress, is

$$s_{t\min} = s_{c\max} = (s_t/2) - \sqrt{s_s^2 + (s_t/2)^2} \tag{9b}$$

The maximum unit shearing stress under this combination of stresses is

$$s_{s\max} = \sqrt{s_s^2 + (s_t/2)^2}, \tag{9c}$$

and the angle θ_s of the planes p–q, 90° apart, on which the stress acts, is given by $\tan 2\theta_s = s_t/(2s_s)$.

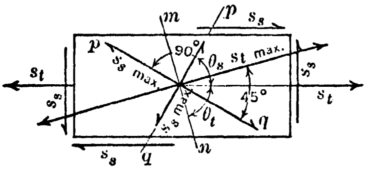

FIG. 14

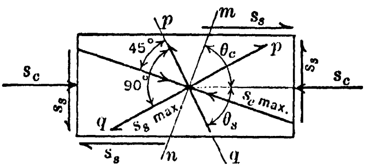

FIG. 15

Where the stresses are shear and compression, Fig. 15, the maximum unit compressive stress is

$$s_{c\max} = (s_c/2) + \sqrt{s_s^2 + (s_c/2)^2} \tag{10a}$$

and the angle θ_c of the plane to which it is normal is given by $\tan 2\theta_c = 2s_s/s_c$. The maximum unit shearing stress is

$$s_{s\max} = \sqrt{s_s^2 + (s_c/2)^2}, \tag{10b}$$

and the angle θ_s of the plane on which it acts is given by $\tan 2\theta_s = -s_c/(2s_s)$. The maximum unit tensile stress for this combination of stresses is,

$$s_{t\max} = s_{c\min} = (s_c/2) - \sqrt{s_s^2 + (s_c/2)^2}. \tag{10c}$$

6. ALLOWABLE STRESS AND FACTOR OF SAFETY

The Allowable Unit Stress or the allowable working unit stress, commonly called **allowable stress** or **working stress**, is the maximum unit stress to which it is considered a member may safely be subjected when in service. The term allowable stress is preferable to working stress since the latter is sometimes used to indicate the actual stress in a material when in service. The allowable unit stresses for different materials for various conditions of service are specified by different authorities on the basis of test or experience. In general, for ductile materials, the allowable stress is considerably less than the yield point.

The Factor of Safety is the ratio of the ultimate strength of the material to the allowable stress. The term was originated for determining the allowable stress. The ultimate strength of a given material divided by an arbitrary factor of safety, dependent upon material and the use to which it is to be put, gives the allowable stress. In present design practice, it is customary to use allowable stress as specified by recognized authorities or building codes rather than this arbitrary factor of safety. One reason for this decreasing importance of the factor of safety is that it is misleading in that it implies a greater degree of safety than actually exists in a material. For example, a factor of safety of 4 does not mean that a member can carry a load four times as great as that for which it was designed. It should also be clearly understood that, even though each part of a machine is designed with the same factor of safety, the machine as a whole does not have that factor of safety. When one part is stressed beyond the proportional limit, or particularly the yield point, the load or stress distribution may be completely changed throughout the entire machine or structure, and its ability to function may thus be changed though no part has ruptured.

Though no definite rules can be given, if a factor of safety is to be used the following circumstances should be taken into account in its selection:

1. When the ultimate strength of the material is known within narrow limits as for structural steel for which tests of samples have been made, when the load is entirely a steady one of a known amount and there is no reason to fear the deterioration of the metal by corrosion, the lowest factor that should be adopted is 3.
2. When the circumstances of 1 are modified by a portion of the load being variable, as in floors of warehouses, the factor should be not less than 4.
3. When the whole load, or nearly the whole, is apt to be alternately put on and taken off, as in suspension rods of floors of bridges, the factor should be 5 or 6.
4. When the stresses are reversed in direction from tension to compression, as in some bridge diagonals and parts of machines, the factor should be not less than 6.
5. When the piece is subjected to repeated shocks, the factor should be not less than 10.
6. When the piece is subjected to deterioration from corrosion the section should be sufficiently increased to allow for a definite amount of corrosion before the piece will be so far weakened by it as to require removal.
7. When the strength of the material or the amount of the load or both are uncertain, the factor should be increased by an allowance sufficient to cover the amount of the uncertainty.
8. When the strains are of a complex character and of uncertain amount, such as those in the crankshaft of a reversing engine, a very high factor is necessary, possibly even as high as 40.
9. If the property loss caused by failure of the part may be large or if loss of life may result, as in a derrick hoisting materials over a crowded street, the factor should be large.

In Table II are the average values of the factors of safety for different conditions as given by Merriman (Mechanics of Materials).

The factors given by different authorities for some materials show a remarkable difference: for example, Rankine specified a factor of safety of 4 for masonry under dead load whereas Unwin specified a factor of 20. This may possibly be explained as follows: If the actual crushing strength of a pier of masonry is known from direct experiment, then a factor of safety of 4 is sufficient for a pier of the same size and quality under a steady load; but if the crushing strength is merely assumed from figures given by authorities which may be an average of a wide range, then a factor of safety of 20 may be none too great. Here the factor of safety is really a "factor of ignorance."

Table II. Average Values of Factor of Safety

Material	Steady stress	Variable stress	Shocks	Material	Steady stress	Variable stress	Shocks
Cast iron	6	10	20	Hard steel	5	8	15
Wrought iron	4	6	10	Timber	8	10	15
Structural steel	4	6	10	Brick and stone	15	25	40

7. REPEATED STRESS

Parts Subjected to Repeated Stress. Where parts of a structure or machine are subjected to varying or repeated loads, the ordinary methods of computing stresses and of determining the strength of materials under static load conditions are not satisfactory. In general, in excess of one-half to ten million repetitions of loading are necessary before the parts come under this classification. Such parts are crankshafts, shafts carrying rotating parts, as in motors and generators, turbine blades, valve parts, piston rods in steam engines, floor beams in elevated railroads, etc.

Character of Failure. Under repeated loadings, failures take place suddenly and without warning. Formerly, it was supposed that vibration caused a change in the structure of the metals, making the fibrous material crystalline and brittle. Thus the term *fatigue of metals* came to be applied to this phenomenon. It is now well known that all metals are crystalline, and the mechanism of "fatigue" failure under repeated stress appears to be that very tiny particles of metal are stressed beyond the elastic limit. As the stress is repeated, a tiny crack, sometimes called a fatigue crack, is formed and progresses until failure occurs. This action is referred to as a *progressive failure.* Therefore, where the load is repeated, anything which causes a concentration of stress is a source of weakness.

Determination of Endurance Limit. The highest unit stress, s, at which a material can be subjected to a very large number of repetitions of loading, N, and still show no evidence of failure is called the *endurance limit.* This is usually found for any given metal by constructing an s-N diagram for that particular metal from data obtained by tests. A piece of metal is so loaded as to produce a given stress. This load is then repeated until failure occurs. Other specimens are then tested at different values of the unit stress, until finally enough points have been obtained to plot a curve. This curve will incline steeply at the higher stresses and gradually flatten out at the lower stresses until it approaches a horizontal line. The unit stress at which the curve becomes horizontal is called the endurance limit. Such a curve plotted to logarithmic scales is shown in Fig. 16. The ordinate of the horizontal portion is the endurance limit. The most common test is that of reversed bending by the rotating beam method, since this specimen is the most easily made and the testing machines are the cheapest. But tests are also made in direct tension, direct shear, direct compression, reversed torsion, and on various combinations of these.

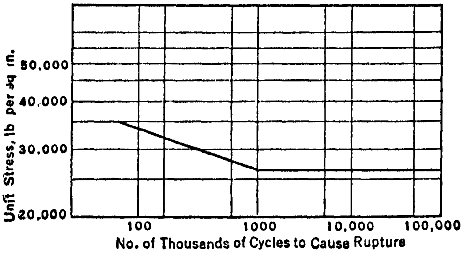

Fig. 16

Values of Endurance Limit. Moore and Kommers, and Moore and Jasper (*Bull. Eng. Exp. Sta.*, Univ. of Ill., Nos. 124 and 136, 1921, 1923) reach a number of conclusions concerning wrought ferrous metals. A summary of the more important of these follows:

1. It is considered as well established that for wrought ferrous metals there is an endurance limit stress below which they will withstand an indefinite number of repetitions of stress.
2. In reversed bending, there is a fairly definite relation between the endurance limit and the ultimate tensile strength and the Brinell hardness number. The endurance limit is about 50 per cent of the ultimate tensile strength, with values ranging between 40 per cent and 60 per cent. The endurance limit is between 200 and 250 times the Brinell hardness number.
3. There is no relation between the endurance limit and impact test results nor repeated-impact test results.
4. The endurance limit in reversed torsion (shear) varies from 48 to 60 per cent of the endurance limit in reversed bending.
5. The endurance limit in reversed axial stress (tension to compression) varies from 56 to 70 per cent of the endurance limit under reversed bending with nearly all the values 60 per cent or above. The reason for this low value is that practically all axial loads are slightly eccentric and cause bending. Irwin (*Proc. A.S.T.M.*, vol. xxv, Pt. II, p. 53, 1925), with a specially designed machine, found the reversed axial stress to be practically the same as that in reversed bending.

A report of Research Committee on Fatigue of Metals (*Proc. A.S.T.M.*, vol. xxx, Pt. I, p. 259, 1930) gives a concise statement of the state of knowledge at that date, which corroborates the above conclusions with the following changes or additions:

1. There is no general relationship between the yield point or the proportional limit and the endurance limit.
2. For cast ferrous metals the endurance limit is about 40 per cent of the tensile strength.
3. For non-ferrous metals there is no definite relationship between the endurance limit and the tensile strength, the values varying between 18 and 50 per cent.
4. For cast ferrous metals the endurance limit is about 26 per cent of the modulus of rupture.
5. For wrought ferrous metals the endurance limit is about 250 times the Brinell number for numbers under 400. For Brinell numbers exceeding 400, the relationship does not hold. For cast ferrous metals and for non-ferrous metals sufficient data are not available to permit judging the degree of correlation.

Table III gives the endurance limit and other properties of a number of ferrous metals. Table IV gives similar information for non-ferrous metals. The values of the endurance limit for heat-treated steels vary according to the treatment, ranging from 29,300 to 68,000 lb per sq in. for a 0.49 per cent carbon steel, from 50,000 to 108,000 lb per sq in. for a 1.20 per cent carbon steel, and from 54,000 to 120,000 lb per sq in. for a 3.50 per cent nickel steel. Table V summarizes the endurance ratios (ratio of ultimate tensile strength to endurance limit) for different types of stress. Moore and Kommers in Fatigue of Metals (McGraw-Hill, New York, 1927), p. 147, state that the ratio of the endurance limit in reversed torsion to the endurance limit in reversed bending averages as follows: Plain carbon steels, 0.55; alloy steels, 0.58; non-ferrous metals, 0.52.

Effects of Scratches and Defects on Endurance Limit of Rolled or Forged Ferrous Metals. The beginning of rupture under repeated stress is supposed to be at a point of discontinuity in the material. The same principle applies to a discontinuity on the outer surface where, in bending or torsion, the stress is greatest. The presence of scratches, sharp corners, or grooves reduces the endurance limit an appreciable amount. Moore and Kommers (*Bull. Eng. Exp. Sta.*, Univ. of Ill., No. 124) obtained the following reductions in the endurance limit, using steel of 0.02 per cent C and 0.49 per cent C, with results the same for each steel. The experiments were performed on bars of 0.40-in. diameter and turned down to 0.275-in. diameter at the bottom of the notch.

Table V. Endurance Ratios for Ferrous Metals under Different Stress Conditions

Character of Stress	Endurance Ratio,* Per Cent		
	Wrought metals	Cast steel	Cast iron, gray
Reversed bending	40–55	42	33–46
Reversed torsion	21–37	......	......
Axial tension, zero to a maximum	......	......	49
Axial compression, zero to a maximum	......	......	59
Axial tension to axial compression	24–40†	......	......

* The ratio of the ultimate tensile strength to the endurance limit.

† With precise loading devices this value has been found to be practically the same as in reversed bending, but such refinement in loading cannot be obtained in practice.

The surface finish has an appreciable effect on the endurance limit. The standard finish used in the experiments of Moore and Kommers was obtained by polishing a smooth turned specimen with No. 0 and 00 emery cloth. Unpolished smooth turned specimens had an endurance limit 8 to 12 per cent lower than those that were polished; a rough turned finish gave a slightly lower value than the smooth turned finish. For cast-iron specimens having a 60° groove with a bottom radius of 5/64 in., the reduction in the endurance limit was only 8 per cent. Clearly, the effect of scratches, grooves, and external discontinuities is not so great in cast iron as in steel, probably because they are a relatively small addition to the large internal discontinuities of the material.

According to the theory of elasticity, a small hole, of diameter less than 1/6 the diameter of the specimen, should cause a stress at the edge of the hole three times the stress based on a uniform stress distribution, and therefore should reduce the endurance limit to

33 per cent of that which would be obtained on a solid specimen. Tests on rotating beams of various steels with a small hole drilled through a diameter gave endurance limits from 50 to 65 per cent of those for the solid beams, showing that these theoretically high stresses do not produce corresponding failures. This is probably due to readjustments in the ductile metal.

Effect of Range of Stress. The endurance limit as determined by a rotating beam is the endurance limit for a complete reversal of stress from tension to compression, and vice versa. The endurance limit is less for a complete reversal than it is for those stress combinations where the stress goes only from a maximum to zero, or from a maximum to a minimum which is above zero. Howell (*Bull. Eng. Exp. Sta.*, Univ. of Ill., No. 136) proposed the empirical relation $s = s_1(r + 3)/2$, where s = endurance limit for the range of stress r; s_1 = endurance limit for completely reversed stress of the same character as s, *i.e.*, direct stress, bending, torsion, etc.; r = ratio of the minimum stress to the maximum stress for a cycle of stress; for instance, if the stress varies from 6000 lb per sq in. compression to 10,000 lb per sq in. tension, the ratio r would be $-6000/+10{,}000 = -0.60$. Using the above notation, a formula was suggested by Moore, Kommers and Jasper (*Proc. A.S.T.M.*, vol. xxii, Pt. II, 1922) where $s = 3s_1/(2 - r)$. This gives values for forged or rolled iron and steel which accord fairly well with tests, being on the safe side. For a complete digest of data, see Report of Research Committee on Fatigue of Metals, *Proc. A.S.T.M.*, vol. xxx, Pt. I, p. 259, 1930.

Effect of Corrosion. If a part is subjected to repeated loads and at the same time to corrosive agencies the endurance limit may be greatly reduced from its normal value as determined in air. McAdam at the U. S. Naval Eng. Exp. Sta., Annapolis (*Proc., A.S.T.M.*, vol. xxvi, Pt. II, p. 224, 1926, the first of many papers), has experimented on various steels with a number of corrosive agents. He found that the endurance limit may be reduced to one-third its normal value. Even so mild an agent as a stream of fresh water may reduce the endurance limit one-half, and salt water or water containing other salts in solution is very destructive. Practically all steels are affected, the corrosion-resistant ones less so than ordinary steels. Steam at 220 lb per sq in., and 700° F, without appreciable amounts of oxygen or liquid water did not greatly affect chromium-iron or nickel-steels, but when these steels were tested in air under a jet of steam their strengths were reduced (Fuller, *Tech. Pub.* No. 294, *A.I.M. & M.E.*, and *Metal Progress*, July, 1931, p. 79).

In *corrosion-fatigue*, the stress need not be high enough to have started fatigue cracks without corrosion. The protective film of oxide breaks down under alternating stress and allows the formation of corrosion pits which progress more rapidly under stress than without it. The pits cause a high concentration of stress at the bottom, and this cycle of the pit increasing the stress and the stress increasing the depth of the pit continues; when the stress has been raised beyond the endurance limit, a fatigue crack starts. Since fatigue action is not a function of time but of the number of reversals of stress, whereas corrosion is a function of time, it has not yet (1935) been possible to obtain "corrosion-fatigue" values which can be used directly in design.

The most effective method of protection is to keep the parts subjected to repeated loads from contact with corrosive agents as much as possible. Where this is not possible, a protective coating of some elastic material, such as varnish, cement, or enamel, will aid. Certain substances called inhibitors, such as sodium chromate, introduced into the corrosive stream or applied in some other way, have been found to help in restoring the protective film on the metal.

8. ENERGY LOADS

Classification of Loads. A static load is one that increases gradually from zero to its full intensity; its effect on a bar has been considered in preceding paragraphs. A suddenly applied load is one that just touches a bar before it is released and then acts at its full intensity from the beginning to the end of the deformation. A moving load is one that is moving when it is brought to bear on the bar; the effect of such a load, which is denoted by the word impact, is much greater than that of a static or a suddenly applied load. Suddenly applied and moving loads are often termed *dynamic loads* or *energy loads*.

Relation between Stored Energy and Size of Member. The external work (see p. 5–08) performed in deforming a bar within the proportional limit is $\frac{1}{2}s^2Al/E$, where s is the unit stress, A is the cross-sectional area of the bar, l is its length, E is the modulus of elasticity. This is also the energy stored in the bar. Since the energy absorbed varies directly as the square of the unit stress, it follows that large amounts of energy will be absorbed by those portions where the stress is high. It is important that where high stresses occur they should be present over as great a length of the member as possible.

If one part of a rod must have a small diameter it is advisable to have as great a length of the rod as possible with the same small diameter, as otherwise there will be a high concentration of energy in a small portion of the member and failure may result. See Seely, Resistance of Materials, 2nd Ed., p. 271.

Effect of Sudden Loads. If a sudden load P be applied to a bar, it will cause deformation ϵl, and the work done by the load will be $P\epsilon l$. Since the external work equals the internal work, $P\epsilon l = s^2Al/2E$, and since $\epsilon = s/E$, $P = sA/2$, or $s = 2P/A$. The unit stress, and also the unit deformation, is double that under an equal load applied gradually.

However, the bar does not maintain equilibrium at the point of maximum stress and deformation, but, after a series of oscillations in which the surplus energy is dissipated in heat, it comes to rest finally with a deformation and stress due to the equal static load.

Stress Due to Live Loads. In structural design two loads are considered, the dead load or weight of the structure and the live load or superimposed loads to be carried. The stresses due to the dead load and to the live loads respectively are computed separately, regarding each as a static load. It is obvious that the stress due to the live load may be greatly increased, depending on the suddenness with which the load is applied. It has been shown above that the stress due to a suddenly applied load is double the stress caused by a static load. The term *coefficient of impact* is used extensively in structural engineering to denote the number by which the computed static stress is multiplied to obtain the value of the increased stress assumed to be caused by the suddenness of application of the live load. If s = static unit stress computed from the live load, and i = coefficient of impact, then the increase of unit stress due to sudden loading is is, and the total unit stress due to the live load is $s + is$. The value of i has been determined by empirical methods and varies according to different conditions. In the building codes of most cities, specified floor loads for buildings include the impact allowance, and no increase is needed for live loads except for special cases of vibration or other unusual conditions. For railroad bridges, the value of i depends upon the proportion of the length of the bridge which is loaded. The Report of the Building Code Committee of the U. S. Bureau of Standards, Minimum Live Loads Allowable for Use in Design of Buildings, 1925, records results of experiments by A. H. Fuller, Iowa State College. A gymnasium balcony carried by steel beams, with one end resting on a masonry wall and the other supported by rods attached to a roof truss, was loaded with a crowd of men and gave the following results:

Action of Crowd	Percentage Increase of Live Load Static Stress Due to Dynamic Effect	
	Suspender rod	Floor beams
Teetering on toes in various ways	30 to 165 Average 65	35 to 155 Average 80
Rising suddenly from a sitting position in chairs	50 to 55	35 to 45
Cheering and giving college yells	10 to 55 Average 35	15 to 50 Average 35

Unpublished tests by L. J. Larson on the concrete stadium at the University of Illinois during football games gave no measurable impact effect when crowds rose during exciting plays. As it is improbable that an ordinary crowd in a public building will act in perfect unison, a coefficient of impact $i = 0.5$ should be sufficient, and $i = 0.8$ is ample, for ordinary light structures. No increase in the static stress is needed when the mass of the structure, as in monolithic concrete, is great. For machinery and for unusual conditions, such as elevator machinery and its supports, each structure should be considered by itself and the coefficient assumed accordingly.

It should be noted that the meaning of the word impact used above differs somewhat from its strict theoretical meaning and as it is used in the next paragraph. The use of the terms impact and coefficient of impact in connection with live load stresses is, however, very general.

Axial Impact on Bars. If a load P is dropped from a height h on to the end of a vertical bar of cross-sectional area A, rigidly secured at the bottom end, there is produced in the bar a unit stress which increases from 0 up to s' with a corresponding total deformation increasing from 0 up to e_1. The work done on the bar is $P(h + e_1)$ which, provided no energy is expended as heat or in giving velocity to the bar, is equal to the energy $\frac{1}{2}s'Ae_1$ stored in the bar; i.e., $P(h + e_1) = \frac{1}{2}s'Ae_1$. If e is the deformation produced by a static load P, then, within the proportional limit, $\frac{e_1}{e} = \frac{s'}{P/A}$, which combined with the previous equation gives

$$s' = s + s\sqrt{1 + \frac{2h}{e}} \quad \text{and} \quad e_1 = e + e\sqrt{1 + \frac{2h}{e}} \tag{11}$$

A wrought-iron bar 1 in. square and 5 ft long under a static load of 5000 lb will be shortened about 0.012 in., assuming that no lateral flexure occurs; but, if a weight of 5000 lb drops on its end from a small height of 0.048 in., a stress of 20,000 lb will be produced.

The formulas above give values of stress and deformation due to impact that are somewhat large, because part of the energy of the applied force is not effective in producing stress but is expended in overcoming the inertia of the bar and in producing local stresses. For light bars, they give approximately correct results.

If the bar is held horizontally and is struck at one end by a weight P moving at a velocity V producing a deformation e_1, then, as above, $\frac{1}{2}s'A\, e_1 = Ph$, where h is the height through which P would have to fall to acquire the velocity V, and is given by $h = V^2/2g$, in which g is the acceleration due to gravity, usually taken as 32.16 ft per sec per sec. Combining with $\frac{e_1}{e} = \frac{s'}{P/A}$, there result

$$s' = s\sqrt{\frac{2h}{e}} \quad \text{and} \quad e_1 = e\sqrt{\frac{2h}{e}} \tag{12}$$

Impact on Beams. If a weight P falls upon a horizontal beam from a height h, producing a maximum deflection y_1 and a maximum unit stress s' in the extreme fiber, the value of s' and y_1 is given by

$$s' = s + s\sqrt{1 + 2h/y} \quad \text{and} \quad y_1 = y + y\sqrt{1 + 2h/y} \tag{13}$$

where s is the extreme fiber unit stress and y is the deflection due to P, considered as a static load. The value of s may be obtained from the flexure formula (p. 5–21); that of y from the proper formula for deflection under a static load.

If a weight P moving horizontally with a velocity V strikes a beam, the ends of which are secured against horizontal movement, the maximum fiber unit stress and the maximum lateral deflection are given by

$$s' = s\sqrt{\frac{2h}{y}} \quad \text{and} \quad y_1 = y\sqrt{\frac{2h}{y}} \tag{14}$$

where s and y are as given above and h is height through which P would have to fall to acquire the velocity V.

These formulas, like those for axial impact on bars, give results larger than those observed in tests, particularly if the weight of the beam is great. For further discussion of this subject, see Seely's Resistance of Materials, 2nd Ed., Chapter 11.

Rupture from Impact. Since the stresses caused by moving loads increase with the velocity of the load, it is obvious that rupture may be caused by impact provided the load has the requisite velocity. The above formulas, however, do not apply, since they are valid only for stresses within the proportional limit. There being no rational formulas for rupture due to impact, the only information available has been obtained through experiment. The relation between the work required for rupture from impact and the work required under static loads has been determined by Hatt. From nearly 200 experiments he determined that the work required for rupture from impact was about 30 per cent greater than that required by static loads. From available test data it does not seem that the ultimate elongation under impact (dynamic) loads is widely different from that under static loads. For the results of a large number of impact tests on cast iron, see *Proc. A.S.T.M.*, vol. xxxiii, Pt. 1, p. 87 ff., 1933.

By Jasper O. Draffin

9. THEORY OF FLEXURE

Types of Beams. A beam is a bar or structural member subjected to transverse loads that tend to bend it. Usually beams are horizontal bars designed to carry vertical loads, but any structural member acts as a beam if bending is induced by external transverse forces.

A Simple Beam (Fig. 1*a*) is a horizontal member that rests on two supports at the ends of the beam. All parts between the supports have free movement in a vertical plane under the influence of vertical loads.

A Fixed Beam, Constrained Beam, or Restrained Beam (Fig. 1*b*) is one that is rigidly fixed at both ends or rigidly fixed at one end and simply supported at the other.

A Continuous Beam (Fig. 1*c*) is a member resting on more than two supports.

A Cantilever Beam (Fig. 1*d*) is a member with one end projecting beyond the point of support, free to move in a vertical plane under the influence of vertical loads placed between the free end and the support.

Phenomena of Flexure. When a simple beam bends under its own weight, the fibers on the upper or concave side are shortened, and the stress acting on them is compression; the fibers on the under or convex side are lengthened and the stress acting on them is tension. In addition to the longitudinal stresses acting on the fibers, shear exists along each cross-section, the intensity of the shear being greatest along the sections at the two supports and zero at the middle section.

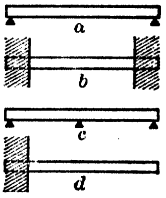

Fig. 1

When a cantilever beam bends under its own weight the fibers on the upper or convex side are lengthened under tensile stresses; the fibers on the under or concave side are shortened under compressive stresses; the shear is greatest along the section at the support and zero at the free end.

The Neutral Surface is that horizontal section between the concave and convex surfaces of a loaded beam, where there is no change in the length of the fibers and no tensile or compressive stresses acting upon them.

The Neutral Axis is the trace of the neutral surface on any cross-section of a beam (Fig. 2).

The Elastic Curve of a beam is the curve formed by the intersection of the neutral surface with the side of the beam, it being assumed that the longitudinal stresses on the fibers are within the elastic limit.

Reactions at Supports. The reactions or upward pressures at the points of support are computed by applying the following conditions necessary for equilibrium of a system of vertical forces in the same plane: (1) The algebraic sum of all vertical forces must equal zero; *i.e.*, the sum of the reactions equals the sum of the downward loads. (2) The algebraic sum of the moments of all the vertical forces must equal zero.

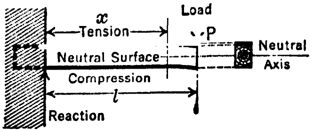

Fig. 2

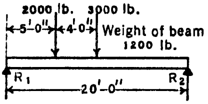

Fig. 3

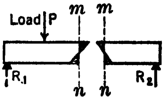

Fig. 4

From the first condition it is evident that in the case of a cantilever beam, where there is but one support, the reaction is equal to the sum of all vertical forces acting downward, comprising the weight of the beam and any loads that come upon it. Where there are two supports and the load is uniformly distributed, as is usually the case of the weight of the beam itself, or if equal concentrated loads are placed at equal distances from the center of the beam, each support carries one-half of the total load and the reactions are equal. If a beam supported at two points is not uniformly loaded each reaction must be computed separately by applying the second condition for equilibrium. Thus in Fig. 3 let R_1 and R_2 be the two reactions of a simple beam 20 ft long weighing 1200 lb, which carries concentrated loads of 2000 lb and 3000 lb at distances of 5 ft and 9 ft, respectively, from the left support. Taking a center of moments for convenience at the left support, and regarding the weight of the beam as a concentrated load applied at its center of gravity

$$+2000 \times 5 + 3000 \times 9 + 1200 \times 10 - R_2 \times 20 = 0. \quad R_2 = 2450 \text{ lb}$$

Taking a center of moments at the right support

$$R_1 \times 20 - 2000 \times 15 - 3000 \times 11 - 1200 \times 10 = 0. \quad R_1 = 3750 \text{ lb}$$

$R_1 + R_2 = 6200$ lb which is equal to the sum of all the loads acting downward.

Conditions of Equilibrium. Imagine a vertical plane cutting the beam, Fig. 4, into two parts at any section *mn*. The external forces acting on either part, comprising the loads and the reaction, are held in equilibrium by the tensile, compressive and shearing stresses acting on the fibers of the cross-section. From the conditions necessary for static equilibrium of a system of forces in one plane the following fundamental laws are deduced for the stresses at any cross-section:

(1) Sum of horizontal tensile stresses = sum of horizontal compressive stresses. (2) Resisting shear = vertical shear. (3) Resisting moment = bending moment.

Vertical Shear. At any cross-section of a beam the resultant of the external vertical forces acting on one side of the section is equal and opposite to the resultant of the external vertical forces on the other side of the section. These forces tend to cause the beam to shear vertically along the section. The value of either resultant, which is a measure of the shearing tendency, is known as the vertical shear at the section considered. It is usually computed by finding the algebraic sum of the vertical forces to the left of the section, that is, it is equal to the left reaction minus the sum of the vertical downward forces acting between the left support and the section.

A Shear Diagram is a graphic representation of the vertical shear at all cross-sections of the beam. Thus in Fig. 5 the ordinates to the line *AOB* represent to scale the intensity of the vertical shear at the corresponding sections of the simple beam. In this case the vertical shear is greatest at the supports where it is equal to the reactions, and it is zero at the center of the span. In the cantilever beam, Fig. 6, the vertical shear is greatest at the point of support where it is equal to the reaction, and it is zero at the free end. Fig. 7 shows graphically the vertical shear on all sections of a simple beam carrying two concentrated loads at equal distances from the supports, the weight of the beam being neglected.

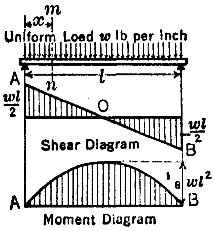

Fig. 5

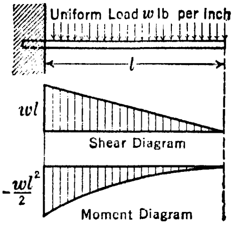

Fig. 6

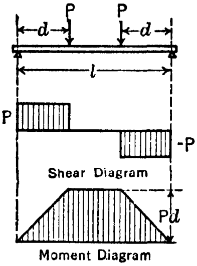

Fig. 7

Resisting Shear. The tendency of a beam to shear vertically along any cross-section due to the vertical shear is opposed by an internal shearing stress at that cross-section known as the resisting shear; it is equal to the algebraic sum of the vertical components of all the internal stresses acting on the cross-section.

If V = vertical shear, pounds; V_r = resisting shear, pounds; s_s = average unit shearing stress, pounds per square inch; and A = area of the section, then at any cross-section

$$V_r = V = s_s A; \quad s_s = \frac{V}{A} \tag{1}$$

The resisting shear is not uniformly distributed over the cross-section, but the intensity varies from zero at the extreme fiber to its maximum value at the neutral axis.

At any point in any cross-section the vertical unit shearing stress, pounds per square inch, is

$$s_s = \frac{VA'c'}{It} \tag{2}$$

where V = total vertical shear, pounds, for the section considered; A' = area, square inches, of cross-section between a horizontal plane through the point where the shear is being found and the extreme fiber on the same side of the neutral axis; c' = distance, inches, from the neutral axis to the center of gravity of the area A'; I = moment of inertia of the section, inches^4; t = width of section at plane of shear, inches. For a solid rectangular beam, the maximum value of the unit shearing stress is

$$s_s = \frac{3V}{2A} \tag{3}$$

where A = total area, square inches, of cross-section of the beam; for a solid circular beam, the maximum unit shearing stress is

$$s_s = \frac{4V}{3A} \tag{4}$$

Horizontal Shear. If at any point within a [illegible] ject to stress, there exists a unit shearing stress along one pla[illegible] there must a[illegible] equal unit shearing stress along a perpendicular plane throu[illegible] at point. For [illegible] this see Laurson and Cox: Properties and Mechanics of Mat[illegible] (John Wiley & [illegible], New York), p. 134. In a beam, at any cross-section where t[illegible] vertical shearing force there must be resultant unit shearing stresses acting on th[illegible] faces of particles which lie at that section. On a horizontal surface of such a [illegible] there is a unit shearing stress equal to the unit shearing stress on a vertical [illegible] of the particle. Equation 2 therefore also gives the horizontal unit shearing str[illegible] any point on the cross-section of a beam.

Bending Moment. The bending m[illegible]ent, or moment, at any cross-section of a beam is the algebraic sum of the moments o[illegible] the external forces acting on either side of the section. It is considered positive when it causes the beam to bend convex downward, hence causing compression in upper fibers and tension in lower fibers of beam. When the bending moment is determined from the forces that lie to the left of the section, it is positive if it acts in a clockwise direction; if determined from forces on the right side, it is positive if it acts in a counter-clockwise direction. If the moments of upward forces are given positive signs, and the moments of downard forces negative signs, the bending moment will always have the correct sign, whether determined from the right or left side. The bending moment should be determined for the side for which the calculation will be simplest.

In Fig. 5 let M be the bending moment, pound-inches, at a section *mn* of a simple beam at a distance x, inches, from the left support, w = weight of the beam per 1 in. of length, and l = length of the beam, inches. Then the reactions are $\frac{1}{2}wl$ and $M = \frac{1}{2}wl.x - \frac{1}{2}x.wx$. For the sections at the supports $x = 0$ or l and $M = 0$. For the section at the center of the span $x = \frac{1}{2}l$ and $M = \frac{1}{8}wl^2 = \frac{1}{8}Wl$, where W is the total weight.

A Moment Diagram (Figs. 5, 6, and 7) shows the bending moment at all cross-sections of a beam. Ordinates to the curve represent to scale the moments at the corresponding cross-sections. The curve for a simple beam uniformly loaded is a parabola showing $M = 0$ at the supports and $M = \frac{1}{8}wl^2 = \frac{1}{8}Wl$ at the center, M being in pound-inches.

The Dangerous Section is the cross-section of a beam where the bending moment is greatest. In a cantilever beam the dangerous section is at the point of support, regardless of the disposition of the loads. In a simple beam it is that section where the vertical shear changes from positive to negative, and may be located graphically by constructing a shear diagram, or numerically by taking the left reaction and subtracting the loads in order from the left until a point is reached where the sum of the loads subtracted equals the reaction. For a simple beam uniformly loaded, the dangerous section is at the center of the span.

Resisting Moment. The tendency to rotate about a point in any cross-section of a beam is due to the bending moment at that section; this tendency is resisted by the resisting moment which is the algebraic sum of the moments of all the horizontal stresses with reference to the same point.

Formula for Flexure. If M = bending moment, M_r = resisting moment of the horizontal fiber stresses, s = unit stress (tensile or compressive) on any fiber, usually that most remote from the neutral surface, and c = distance of that fiber from the neutral surface, then

$$M = M_r = \frac{sI}{c}; \quad s = \frac{Mc}{I} \tag{5}$$

where I is the moment of inertia of the cross-section with respect to its neutral axis. If s is in pounds per square inch, then M must be in pound-inches, I in inches^4, and c in inches. (For proof of the relation $M = sI/c$, see Seely's Resistance of Materials.)

Formula 5 is the basis of the design and investigation of beams. It is true only when the maximum horizontal fiber stress s does not exceed the proportional limit of the material.

The Moment of Inertia is the sum of the products of each elementary area of the cross-section multiplied by the square of the distance of that area from the assumed axis of rotation, or

$$I = \Sigma r^2 \, \Delta A = \int r^2 \, dA \qquad (6)$$

in which Σ is the sign of summation, ΔA = an elementary area of the section, and r = distance of ΔA from the axis. It is evident that the moment of inertia is greatest in those sections (such as I-beams) having much of the area concentrated at a distance from the axis. Unless otherwise stated the neutral axis is the axis of rotation considered. I is usually expressed in inches^4.

Modulus of Rupture. To determine the ultimate strength of a material in bending, a beam is loaded to rupture and the maximum load ·nich it carries is noted. The flexure formula, $s = Mc/I$, is true only for stresses within the proportional limit of the material. Therefore, the value, s, of the rupture strength and ohed from the breaking load by this equation is incorrect. However, the equation section and the nominal value so found is called the *modulus of rupture*, which is a meThe valthe ultimate load-carrying capacity of the beam. If the strengths in tension andhe vertession are different, the modulus of rupture is intermediate between the two. It is m oe noted that the modulus of rupture does not express the actual stress in the extreme inber of a beam, but is a quantity useful only as a basis of comparison.

The Section Modulus is the factor I/c in the flexure formula. It is a measure of the capacity of a section to resist any bending moment to which it may be subjected. The section modulus is expressed in inches^3. For values of I and I/c for simple shapes used as beam sections, see Table I. Properties of standard structural shapes are given in Tables 64 to 70, Section 1, and properties for other geometric sections in Table II, p. 4–20.

Table I. Properties of Sections of Beams *

Section of beam	Moment of inertia, I, inches^4	Section modulus, I/c, inches^3	Radius of gyration, k, inches
	$bd^3/12$	$bd^2/6$	$d/\sqrt{12} = 0.289d$
	$\dfrac{b_1d_1^3 - b_2d_2^3}{12}$	$\dfrac{b_1d_1^3 - b_2d_2^3}{6d_1}$	$\sqrt{\dfrac{b_1d_1^3 - b_2d_2^3}{12(b_1d_1 - b_2d_2)}}$
	$\pi d^4/64$	$\pi d^3/32$	$d/4$
	$\pi(d_1^4 - d_2^4)/64$	$\pi(d_1^4 - d_2^4)/32d_1$	$\sqrt{d_1^2 + d_2^2}/4$
	$bd^3/36$	$bd^2/24$ (min.)	$d/\sqrt{18} = 0.236d$

* See also Table II, p. 4–20.

Elastic Deflection of Beams. When a beam bends under load, all points of the elastic curve except those over the supports are deflected from their original positions. The radius of curvature ρ of the elastic curve at any section is expressed as

$$\frac{EI}{M} \qquad (7)$$

where E = the modulus of elasticity of the material, pounds per square inch; I = moment of inertia, inches^4, of the cross-section with reference to its neutral axis; and M = bending moment, pound-inches, at the section considered. Where there is no bending moment ρ is infinity and the curve is a straight line; where M is greatest ρ is smallest and the curvature, therefore, is greatest.

If the elastic curve be referred to a system of coordinate axes in which x represents horizontal distances, y vertical distances, and l distances along the curve, the value of ρ by the aid of the calculus is found to be $d^3l/dx.d^2y$. Substituting this value in the expression $\rho = EI/M$ and assuming that dx and dl are practically equal there results the following differential equation of the elastic curve which applies to all beams when the elastic limit of the material is not exceeded:

$$EI\frac{d^2y}{dx^2} = M \tag{8}$$

Equation 8 is used to determine the deflection of any point of the elastic curve by regarding the point of support as the origin of the coordinate axis and taking y as the vertical deflection at any point on the curve and x as the horizontal distance from the support to the point considered. The values of E, I, and M are substituted and the expression is integrated twice, giving proper values to the constants of integration, and the deflection y is determined for any point. See Table III.

Example. The cantilever beam shown in Fig. 2 has a length = l, inches, and carries a load P, pounds, at the free end. It is required to find the deflection of the elastic curve at a point distant x, inches, from the support, the weight of the beam being neglected.

The moment $M = -P(l - x)$; substituting in (8), the equation for the elastic curve becomes $EI(d^2y/dx^2) = -Pl + Px$. Integrating and determining the constant of integration by the condition that $dy/dx = 0$ when $x = 0$, there results $EI(dy/dx) = -Plx + {}^1/_2Px^2$. Integrating a second time and determining the constant by the condition that $x = 0$ when $y = 0$, there results $EIy = -{}^1/_2Plx^2 + {}^1/_6Px^3$, which is the equation of the elastic curve. When $x = l$ the value of y, or the deflection in inches at the free end, is found to be $-Pl^3/3EI$.

Deflection Due to Shear. The deflection of a beam as computed by the ordinary formulas is that due to flexural stresses only. In short beams the deflection due to vertical shear is sometimes appreciable and may need to be considered. Because of the non-uniform distribution of the shear over the cross-section of the beam, computing the deflection due to shear by exact methods is difficult. It may be approximated by $y_s = M/AE_s$, where y_s = deflection, inches, due to shear; M = bending moment, pound-inches, at the section where the deflection is calculated; E_s = modulus of elasticity in shear, pounds per square inch; A = area of cross-section of beam, square inches (see Seely's Resistance of Materials, 2nd Ed., p. 136). Swain says (Strength of Materials, McGraw-Hill Book Co., p. 223) that for a rectangular section the ratio of deflection due to shear, to deflection due to bending, will be less than 5 per cent, so long as the depth of the beam is less than ${}^1/_8$ of the length.

10. BEAMS OF UNIFORM CROSS-SECTION

Design Procedure. In designing a beam the procedure is: (1) Compute the reactions. (2) Determine the position of the dangerous section and the bending moment at that section. (3) Divide the maximum bending moment (expressed in pound-inches) by the allowable unit stress (expressed in pounds per square inch) to obtain the minimum value of the section modulus. (4) Select a beam section with a section modulus equal to or slightly greater than the section modulus required.

Web Shear. A beam designed in the above manner is safe against rupture of the extreme fibers due to bending in a vertical plane, and usually the cross-section will have sufficient area to sustain the shearing stresses with safety. For short beams carrying heavy loads, however, the vertical shear at the supports is large, and it may be necessary to increase the area of the section to keep the unit shearing stress within the limit allowed. For steel beams, the average unit shearing stress is computed by $s_s = V/A$, where V = total vertical shear, pounds; and A = area of web, square inches. For allowable average unit shearing stresses in cross-section of web of girders and rolled steel beams, as specified by different authorities, see Table II. For timber beams, see Horizontal Shear in Timber Beams, p. 5–25.

Miscellaneous Considerations. Other considerations which will influence the choice of section under certain conditions of loading are: (1) The maximum vertical deflection that may be permitted in beams coming in contact with plaster. (2) The danger of failure by sidewise bending in long beams unbraced against lateral deflection. (3) The danger of failure by the buckling of the web of steel beams of short span carrying heavy loads. (4) The danger of failure by horizontal shear, particularly in wooden beams.

Table II. Allowable Unit Stresses for Structural Steel as Specified by Different Authorities

All stresses in pounds per square inch. l = length of member; b = width of flange; k = radius of gyration; d = depth of web plate; t = thickness of web plate; all dimensions in inches.

Character of Stress	Report of U. S. Bureau of Standards		A.I.S.C. 1934, New York City	A.R.E.A
	Acceptable Steel *	Standard Steel		
Axial tension	16,000	18,000	18,000	16,000
Direct compression	12,500	14,000	18,000	12,500
Compression in columns	$16{,}000 - 60l/k$ Max. 12,500	$18{,}000 - 70l/k$ Max. 14,000	$\dfrac{18{,}000}{1 + l^2/(18{,}000k^2)}$ Max. 15,000	$15{,}000 - 50l/k$ Max. 12,500
Fiber stress in flexure in tension or in compression where l/b is 15 or less	16,000	18,000	18,000	16,000
Compressive fiber stress in flexure for l/b greater than 15 and not exceeding 40	$19{,}600 - 240l/b$	$22{,}000 - 270l/b$	$\dfrac{20{,}000}{1 + l^2/(2000b^2)}$	$16{,}000 - 150l/b$
Fiber stress on pins	24,000	27,000	27,000	24,000
Bearing on plane faced or rolled surfaces	24,000	27,000	....	24,000
Shear in gross section of web of girders or rolled beams where d/t does not exceed value indicated as Q.	$Q = 43$ 10,700	$Q = 43$ 12,000	$Q = 60$ 12,000	10,000

* Steel acceptable to the building official but the origin and physical characteristics of which are not determined.

† New York specifies no values beyond $Q = 60$.

Vertical Deflection. When a beam is to be used to support or come in contact with materials like plaster, which may be broken by excessive deflection of the beam, it is usual in practice to select such a beam that the maximum deflection will not be greater than $^1/_{360}$ of the span.

It may be shown that for a simple beam, supported at the ends, with a total uniformly distributed load W, pounds, the deflection, inches, is

$$y = 30\frac{sL^2}{Ed} \tag{9}$$

where s = allowable fiber unit stress, pounds per square inch; L = span of beam, feet; E = modulus of elasticity, pounds per square inch; d = depth of beam, inches.

If the deflection of a steel beam is to be less than $1/360$ of the span, it may be shown from equation 9 that, for a maximum allowable fiber stress of 18,000 lb per sq in., the limit of span in feet is approximately 1.8 times the depth of the beam in inches.

For the deflection due to the impact of a moving load falling on a beam, see p. 18.

Lateral Deflection. When a beam carries vertical loads, the tensile stresses in the fibers tend to hold the tension flange of the beam in line, but the compressive stresses tend to cause lateral bending of the compression flange. To obtain security against failure of long beams by excessive lateral deflection, sidewise bracing of the compresson flange should be used or the allowable unit stress for the compression fibers should be reduced. The specifications for steel structures of the American Bridge Company provide that "the lateral unsupported length of beams and girders shall not exceed 40 times the width of the compression flange. When the unsupported length l, inches, exceeds 10 times the width b, inches, of the compression flange, the stress per square inch shall not exceed $(19,000 - 300\,l/b)$." The values specified by other authorities are given in Table II. See Examples in Beam Design, p. 5–30.

Buckling of the Web. When a short-span steel beam, carrying heavy concentrated loads, has sufficient web thickness safely to resist shearing stresses, there is still a possibility that the beam is overloaded when the web is considered as a long slender column. The probability of this type of failure is not great if the web thickness is a relatively large percentage of the depth of beam, but it is great if the web is thin and the depth of the beam relatively large. Failure of the web by buckling may be guarded against by increasing its thickness, or by riveting stiffening angles to it. The A.I.S.C. specifications require stiffeners to be placed on the webs of rolled beams and plate girders at the ends, at point of concentrated loads, and at other points where h, the clear distance between flanges, inches, is more than $85t\sqrt{18,000(A/V) - 1}$, where t = thickness of web, inches; A = gross area of web, square inches; and V = total vertical shear at the section. Where stiffeners are required, the distance between them shall not be more than $85t\sqrt{18,000(A/V) - 1}$ inches or more than 6 ft.

Also, the web over a support may crush, if the end bearing is too short; with a thick web, crushing at the junction of the web and flange may occur, but with a thin web and deep beam the web probably will buckle because of column action before it will crush. Security against this excessive stress in the web may be provided by stiffening angles riveted to the web and bearing against the flanges over the support. Such stiffening angles should be placed either directly over the support or at a distance from the support equal to the depth of the beam. If stiffening angles are not used, the allowable reaction recommended by the A.I.S.C. (A.I.S.C.: Steel Construction, 1934) is given by $R = s_b t(a + d/4)$, where $s_b = 18,000/[1 + (d^2/6000t^2)]$, with a maximum of 15,000 lb per sq in.; R = allowable end reaction, pounds; s_b = allowable web crippling unit stress, pound per sq in.; t = web thickness, inches; a = length of bearing, inches; d = depth of beam, inches.

When the loading reaction exceeds the value of R, the web must be stiffened or additional length of bearing provided. In no case may the loading reaction exceed the maximum web shear V. Lack [illegible] lateral support for the top flange of the beam at the reaction point so decre[illegible] strength of the web as to render such practice inadmissible. For t[illegible] e *Bull.* Nos. 68, 86, and 241, *Eng. Exp. Sta.*, Univ. of Ill.

Horizontal Shea[illegible]ns. (See Horizontal Shear, p. 5–21.) In beams of a homogeneous material which ca[illegible] stand equally well shearing stresses in any direction, the vertical and horizontal shearing stresses are equally important. In timber, however, the shearing strength along the grain is much less than that perpendicular to the grain, and hence the beams may fail owing to horizontal shear. Short wooden beams should be checked for horizontal shear in order that the allowable unit shearing stress along the grain shall not be exceeded. See Example 4, p. 5–30.

Restrained Beams. A beam is considered to be restrained if one or both ends are not free to rotate. This condition exists if a beam is built into a masonry wall at one or both ends, if it is riveted or otherwise fastened to a column, or if the ends projecting beyond the supports carry loads which tend to prevent the tilting of the ends which would naturally occur as the beam deflects. The shears and moments given in Table III for fixed end conditions are seldom if ever attained, since the restraining elements themselves deform and reduce the magnitude of the restraint. This reduction of restraint decreases the negative moment at the support and increases the positive moment in the central portion of the span. The amount of restraint which exists is a matter which must be judged for each case in the light of the construction used, the rigidity of the connections, and the relative sizes of the connecting members.

Table III. Bending Moment, Vertical Shear, and Deflection of Beams of Uniform Cross-section under Various Conditions of Loading

P = concentrated loads, lb.
R_1, R_2 = reactions, lb.
w = uniform load per unit of length, lb per in.
W = total uniform load on beam, lb.
l = length of beam, in.
x = distance from support to any section, in.
E = modulus of elasticity, lb per sq in.

I = moment of inertia, in.^{4}
V_x = vertical shear at any section, lb.
V = maximum vertical shear, lb.
M_x = bending moment at any section, lb-in.
M = maximum bending moment, lb-in.
y = maximum deflection, in.

Safe Loads on Simple Beams. By substituting in the flexure formula, p. 5–21, the value of M for a simple beam uniformly loaded as given in Table III, the expression

$$W = \frac{2}{3}s\frac{S}{L} \tag{10}$$

is obtained, where W = total load, pounds; s = extreme fiber unit stress, pounds per square inch; S = section modulus, inches^3; L = length of span, feet.

If s is taken as the maximum allowable fiber unit stress, equation 10 gives the maximum allowable load on the beam. Most building codes permit a value of s = 18,000 lb per sq in. for quiescent loads. For this value of s, equation 10 becomes

$$W = 12{,}000\frac{S}{L} \tag{11}$$

Tables of safe loads, based on equation 11, for various structural steel beams may be found in the A.I.S.C. Steel Construction, 1934, and in Kent's Handbook for Mechanical Engineers.

If the load is concentrated at the center of the span, the safe load is one-half the value given by equation 11. If the load is neither uniformly distributed nor concentrated at

* Stress in tension. The working stresses recommended for fiber stress in bending may be safely used for tension parallel to grain.

† American lumber standards. Basic provisions for American lumber standards grades are published by the U. S. Dept. of Commerce, Simplified Practice Recommendation No. 16, Lumber, revised July 1, 1926; specifications for grades conforming to American lumber standards are published in the 1933 Standards A.S.T.M., and in *Amer. Ry. Eng. Assoc. Bull.*, vol. xxx, No. 314, Feb. 1929.

‡ Exact figures given. In order to preserve the exact numerical relations among working stresses for grades involving rate of growth and density requirements, the values for Douglas fir (western Wash. and Ore.) and for southern yellow pine have not been rounded off, as have the values for the other species.

the center of the span, the beam must, in general, be designed as in the problems below. For some special conditions of loading, however, it is possible to find an equivalent uniformly distributed load (see A.I.S.C. Steel Construction, 1934, pp. 298 et seq.), in which case tables of safe loads may be used. The equations above are for beams laterally supported and are for flexure only. The other factors which influence the strength of the beam (see p. 5-23 et seq.) must still be considered.

Use of Tables in Design. Table III gives formulas for the maximum moment, vertical shear, and deflection under usual conditions of loading. Elements of various sections are given in Table I, p. 5-22. Elements of standard steel sections are given in Section 1.

Table IV gives the allowable unit stresses for timber in bending; in Table V are the allowable unit stresses for timber in compression and shear.

Examples in Beam Design: (1) Concentrated Loads. Find the beam section required to carry loads W_1, W_2, W_3, applied at points of a 15-ft span simple beam as follows: W_1 (assumed weight of beam) 40 lb per ft = 600 lb; W_2 = 10,000 lb at 5 ft from left support; W_3 = 8000 lb at 9 ft from left support. Computing the reactions

$$(R_1 \times 15) - (600 \times 7.5) - (10{,}000 \times 10) - (8000 \times 6) = 0$$
$$R_1 = 10{,}166 \text{ lb.}$$
$$-(R_2 \times 15) + (600 \times 7.5) + (10{,}000 \times 5) + (8000 \times 9) = 0$$
$$R_2 = 8433 \text{ lb.}$$

The dangerous section is directly under W_2, as at this point the vertical shear passes from positive to negative. The moment at this point is

$$M = (10{,}166 \times 5) - (5 \times 40 \times 2.5) = 50{,}330 \text{ lb-ft} = 603{,}960 \text{ lb-in.}$$

For an allowable unit stress of 18,000 lb per sq in., $I/c = 603{,}960/18{,}000 = 33.56$ in.$^3 = I/c$.

In Table 65, Section 1, a section modulus larger than the above is found in a 12-in., 31.8-lb American Standard beam which is, therefore, selected. If this section is used it will be necessary to support the compression flange by bracing to prevent lateral deflection, as the span length is 36 times the width of the flange. If bracing cannot be used a smaller allowable unit stress and, therefore, a larger section will be required. This larger section may be found as follows: Assume that a 12-in., 40.8-lb American Standard beam, which has a flange width b = 5.25 in., may be used. The allowable unit stress by the A.I.S.C. specifications (see Table II) is

$$= \frac{20{,}000}{1 + \frac{l^2}{2000b^2}} = \frac{20{,}000}{1 + \frac{180^2}{2000 \times 5.25^2}} = 12{,}600 \text{ lb per sq in.}$$

$I/c = 603{,}960/12{,}600 = 47.9$ in.^{3} Thus a 12-in., 40.8-lb beam which has an I/c of 44.8 in.^{3} is too small; a 12-in., 50-lb, I/c = 50.3 in.^{3}, or a 15-in., 42.9-lb, I/c = 58.9 in.^{3} beam will be satisfactory.

2. Uniform Load. Select a beam section required to support a superimposed load of 27,000 lb. uniformly distributed over a simple beam with a span of 15 ft, assuming the beam to be braced against lateral deflection.

The beam to be used might be determined directly from a table of safe loads (see Safe Loads, p. 5-28). Such tables are given in Kent's Handbook for Mechanical Engineers. A solution can also be obtained by finding the maximum bending moment as follows:

For a uniformly distributed load, the dangerous section is at the center of the beam. The bending moment at this point (see Table III) is

$$M = \frac{Wl}{8} = \frac{27{,}000 \times 15 \times 12}{8} = 607{,}500 \text{ lb-in.}$$

For an allowable unit stress of 18,000 lb per sq in.,

$$s = \frac{607{,}500}{18{,}000} = 33.75 \text{ in.}^3$$

Referring to Table 65, Section 1, the section modulus of a 12-in., 31.8-lb American Standard beam is 36.0 in.^{3} The maximum safe load for this beam is

$$W = \frac{2sS}{3L} = \frac{2 \times 18{,}000 \times 36}{3 \times 15} = 28{,}800 \text{ lb}$$

The weight of this beam is 31.8 × 15 = 477 lb, making the actual total load 27,477 lb, which is less than the safe load for the beam selected, and hence this beam is satisfactory.

3. Wooden Beams. Design a southern pine girder of common structural grade to carry a load of 9600 lb, uniformly distributed over a 16 ft span simple beam in the interior of a building.

$$M = Wl/8 = 9600 \times 16 \times 12/8 = 230{,}400 \text{ lb-in.}$$

For an allowable unit stress of 1200 lb per sq in. (see Table IV) $I/c = 230{,}400/1200 = 192$ in.^{3} Referring to Table I, p. 5-22, the section modulus of a rectangular section is $bd^2/6$. Assume b = 8 in.; then $8d^2/6 = 192$, from which $d = \sqrt{144} = 12.0$ in. A girder 8 by 12 in. is tentatively selected.

4. Check the horizontal shear in the 8 by 12 wooden girder designed in example 3 above.

Maximum shearing stress (horizontal and vertical) is at the neutral surface over the supports. Using formula 3 for horizontal shear in a solid rectangular beam, p. 5-21,

$$V = 9600/2 = 4800, \quad A = 8 \times 12$$

$$s_s = \frac{3V}{2A} = \frac{3 \times 4800}{2 \times 96} = 75 \text{ lb per sq in.}$$

According to Table V, the safe horizontal unit shearing stress for common grade southern yellow pine is 88 lb per sq in. Since the actual horizontal unit shearing stress is less than this, the beam will be satisfactory.

Table V. Allowable Unit Stresses for Timber in Compression and Shear

Recommended by the Forest Products Laboratory, U. S. Dept. of Agriculture.*

All values are in pounds per square inch.

* See footnote (†), Table IV.

† See footnote (‡), Table IV.

‡ The values for modulus of elasticity are average for species, and not safe working stresses. They may be used as given for computing average deflection of beams. To prevent sag in beams, values one-half those given should be used. For safe loads for long columns, values one-third those given should be used.

§ Values given are for the Select grade. Working stresses in compression, perpendicular to the grain, for common grades of Douglas fir (western Wash. and Ore.) and southern yellow pine are 325, 225, and 200, respectively, for continuously dry, occasionally wet but quickly dried, and more or less continuously damp or wet conditions.

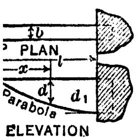
‖ **Joint details. The shearing stresses for joint details may be taken for any grades as 50% greater than the horizontal shear values for the Select grade.**

11. BEAMS OF UNIFORM STRENGTH

A beam of uniform strength is one in which the dimensions are such that the maximum fiber stress s is the same throughout the length of the beam. The form of the beam is determined by finding the areas of various cross-sections from the flexure formula $M = sI/c$, keeping s constant and making I/c vary with M. For a rectangular section of width b and depth d, the section modulus $I/c = {}^1/_6 bd^2$ and, therefore, $M = {}^1/_6 sbd^2$. By making bd^2 vary with M. the dimensions of the various sections are obtained. Table VI gives the dimensions b and d, at any section, the maximum fiber unit stress s, and the maximum deflection y, of some rectangular beams of uniform strength. In this table, the bending moment has been assumed to be the controlling factor. On account of the vertical shear near the ends of the beams, the area of the sections must

Table VI. Rectangular Beams of Uniform Strength *

s = maximum fiber unit stress, pounds per square inch; E = modulus of elasticity; w = uniform load, pounds per inch; d = depth of beam, inches; b = width of beam, inches; y = maximum deflection, inches. All other dimensions in inches.



I. CANTILEVER BEAM LOADED AT FREE END

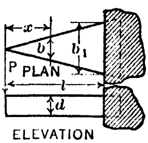
Width is constant. Depth varies.

$d = d_1\sqrt{x/l}$

$s = 6\,Pl/bd_1^2$

$y = 8\,Pl^3/Ebd_1^3$

Elevation is formed by a straight line and a parabola with its vertex at the loaded end.



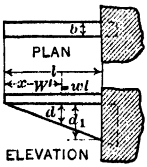
II. CANTILEVER BEAM LOADED AT FREE END

Depth constant. Width varies.

$b = b_1x/l$

$s = 6Pl/b_1d^2$

$y = 6Pl^3/Eb_1d^3$



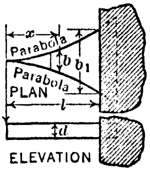
III. CANTILEVER BEAM UNIFORMLY LOADED

Width is constant. Depth varies.

$d = (x/l)d_1$

$s = 3\,wl^2/bd_1^2$

$y = 6wl^4/bEd_1^3$



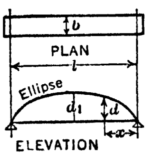
IV. CANTILEVER BEAM UNIFORMLY LOADED

Depth is constant. Width varies.

$b = b_1x^2/l^2$

$s = 3wl^2/b_1d^2$

$y = 3wl^4/b_1Ed^3$



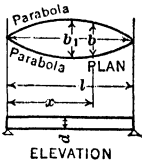
V. SIMPLE BEAM UNIFORMLY LOADED

Width is constant. Depth varies.

$$d = \sqrt{\frac{4d_1^2(lx - x^2)}{l^2}}$$

$$s = \frac{3wl^2}{4bd_1^2}$$

Elevation is formed by a straight line and an ellipse.



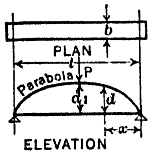
VI. SIMPLE BEAM UNIFORMLY LOADED

Depth is constant. Width varies.

$$b = \frac{4b_1}{l^2}(lx - x^2)$$

$$s = \frac{3\,wl^2}{4\,b_1d^2}$$

Plan is two parabolas, with vertices at center of span.



VII. SIMPLE BEAM LOADED AT CENTER OF SPAN

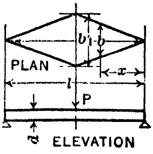
Width is constant. Depth varies.

$d = d_1\sqrt{2x/l}$

$$s = \frac{3}{2}\,\frac{Pl}{bd_1^2}$$

$$y = \frac{1}{2}\,\frac{Pl^3}{Ebd_1^3}$$

Elevation is a parabola with vertices at points of support.



VIII. SIMPLE BEAM LOADED AT CENTER OF SPAN

Depth is constant. Width varies.

$b = 2b_1x/l$

$$s = \frac{3}{2}\,\frac{Pl}{b_1d^2}$$

$$y = \frac{3}{8}\,\frac{Pl^3}{Eb_1d^3}$$

Plan is two triangles with vertices at points of support.

---

* The sections of the beams near the ends must be increased over the amounts shown to resist the vertical shear expressed by the formula $s = {}^3/_2 V/A$.

be increased over that given by an amount necessary to keep the unit shearing stress within the allowable unit shearing stress. The discussion of beams of uniform strength, though of considerable theoretical interest, is of little practical value since the cost of fabrication will offset any economy in the use of the material. A plate girder in a bridge or a building is an approximation in practice to a steel beam of uniform strength.

12. CURVED BEAMS

The derivation of the flexure formula, $s = Mc/I$, assumes that the beam is initially straight; therefore, any deviation from this condition introduces an error in the value of the stress. If the curvature is slight the error involved is not large, but in beams with a large amount of curvature, as hooks, chain links, frames of punch presses, etc., the error involved in the use of the ordinary flexure formula is considerable. The effect of the curvature is to increase the stress in the inside and to decrease it on the outside fibers of the beam and to shift the position of the neutral axis from the centroidal axis toward the concave or inner side.

The correct value for the fiber unit stress may be found by introducing a correction factor in the flexure formula, *viz.*, $s = KMc/I$; the factor K depends on the shape of the beam and on the ratio R/c, where R = distance, inches, from the centroidal axis of the section to the center of curvature of the central axis of the unstressed beam; and c = distance, inches, of centroidal axis from the extreme fiber on the inner or concave side. Seely's Advanced Mechanics of Materials contains an analysis of curved beams and also Table VII which gives values of K for a number of shapes and ratios of R/c. For slightly different shapes or proportions K may be found by interpolation with a fair degree of approximation.

13. CONTINUOUS BEAMS

As in simple beams, the expressions $M = sI/c$ and $s_s = V/A$ govern the design and investigation of beams resting on more than two supports. In the case of continuous beams, however, the reactions cannot be obtained in the manner described for simple beams. Instead, the bending moments at the various sections must be determined, and from these values the vertical shears at the sections and the reactions at the supports may be derived.

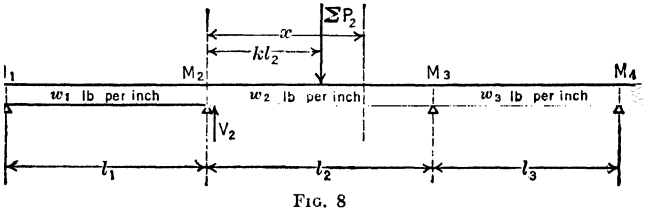


FIG. 8

Consider the second span of length l_2, in., of the continuous beam in Fig. 8. The vertical shear V_x at any section distant x, in., from the left support of the span is equal to the algebraic sum of all the vertical forces on one side of the section. Thus, if V_2 = the vertical shear at a section to the right of, but infinitely close to, the left support, w_2x = the uniform load and ΣP_2 = the sum of the concentrated loads along the distance x, applied at a distance kl_2 from the left support, k being a fraction less than unity, then

$$V_x = V_2 - w_2x - \Sigma P_2 \tag{12}$$

At any section distant x from the left support the bending moment is equal to the algebraic sum of the moments of all forces on one side of the section. If M_2 is the moment, lb-in., at the support to the left,

$$M_x = M_2 + V_2\,x - (w_2\,x^2/2) - \Sigma P_2(x - kl_2) \tag{13}$$

Assume that $x = l_2$. Then M_x becomes the moment M_3 at the next support to the right, and the expression may be written

$$V_2l_2 = M_3 - M_2 + (w_2l_2^2/2) + \Sigma P_2(l_2 - kl_2) \tag{14}$$

From the expressions 12, 13, and 14 it is evident that the bending moment M_x and the shear V_x at any section between two consecutive supports may be determined if the bending moments M_2 and M_3 at those supports are known.

* Y_0 is distance from centroidal axis to neutral axis, where beam is subjected to pure bending.

To determine the bending moments at the supports an expression known as the ***theorem of three moments*** is used. This gives the relation between the moments at any three consecutive supports of a beam. For beams with the supports on the same level and uniformly loaded over each span the expression is:

$$M_1l_1 + 2M_2(l_1 + l_2) + M_3l_2 = -\,{}^1/_4w_1l_1^3 - {}^1/_4w_2l_2^3 \tag{15}$$

in which M_1, M_2 and M_3 are the moments at three consecutive supports, l_1 the length between the first and second support, l_2 the length between the second and third support, w_1 the uniform load per lineal unit over the first span and w_2 the uniform load per lineal unit over the second span. When both spans are of equal length and when the load on each span is the same, $l_1 = l_2$, $w_1 = w_2$, and the above expression reduces to

$$M_1 + 4M_2 + M_3 = -\,{}^1/_2wl^2 \tag{16}$$

which applies to most cases in practice.

Formulas 15 and 16 are used as follows: For any continuous beam of n spans there are $(n + 1)$ supports. Assuming the ends of the beam to be simply supported without any overhang, the moments at the end supports are zero and there are, therefore, $(n - 1)$ moments at the other supports to be determined. This may be done by writing $(n - 1)$ equations of the form of 15 or 16 for each support. These equations will contain $(n - 1)$ unknown moments and their solution will give values of M_1, M_2, M_3, etc., expressed as coefficients of wl^2. The shear V_1 at any support may be determined by substituting values of M_1 and M_2 in formula 14 and the bending moment at any point in any span may be obtained by formula 13. The shear at any point in any span may be determined from formula 12.

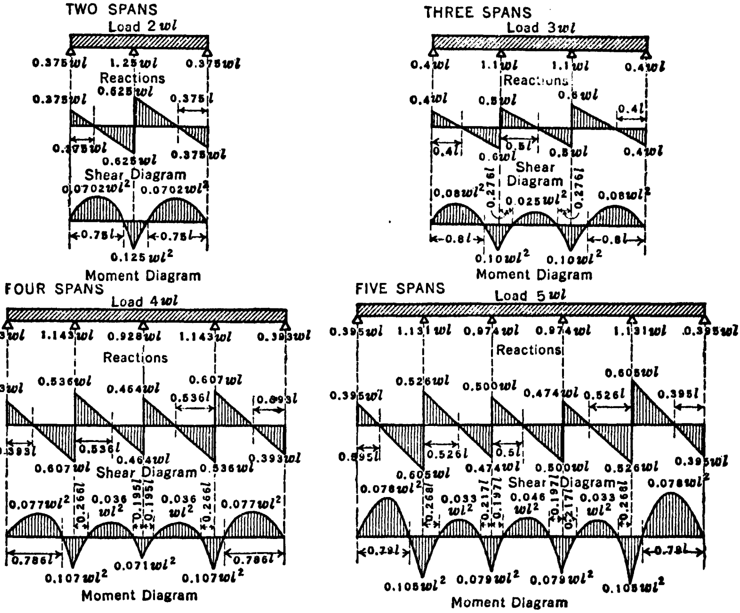

Fig. 9

Fig. 9 gives values and diagrams for the reactions, shears, and moments at all sections of continuous beams uniformly loaded up to five spans. Note that the reaction at any support is equal to the sum of the shears to the right and to the left of that support.

14. AXIALLY END-LOADED BEAMS

(Condensed from Seely, Resistance of Materials, 2nd Ed., Chapter VII)

Deflection of Beam Negligible. When a beam is subjected to an axial end load as well as to a transverse bending load, the resultant unit stress developed at any point in the beam is the algebraic sum of the unit stresses produced by each of the loads acting independently of each other. If the beam of cross-sectional area A, square inches, is considered so short that its deflection under load may be neglected, the unit stress produced at any cross-section of the beam by an axial load P, pounds, is P/A. The maximum unit stress (tensile or compressive), pounds per square inch, due to the transverse or bending load is given by $s = M/(I/c)$ where M, pound-inches, is the maximum bending moment due to this load; I, inches^4, is the moment of inertia of the cross-section with respect to the neutral axis; c, inches, is the distance from the neutral axis to the extreme fiber. If the axial load is compressive, the maximum unit stress is compressive, occurring at the top of the beam, and is

$$s = \frac{P}{A} + \frac{Mc}{I} \tag{17}$$

The unit stress on the bottom fiber may be either tensile or compressive according as Mc/I is larger or smaller than P/A. If the longitudinal load P were a tensile load, the maximum unit stress would occur on the bottom fiber and would be a tensile stress.

Deflection of Beam Not Negligible. If the deflection of the beam is not negligible, the load P above cannot be considered to be an axial load with respect to any cross-sections except the end sections. The longitudinal load then has a moment arm equal to the deflection, and the stress due to this moment should be added algebraically to that caused by the other moments or loads. The stress due to deflection, y, inches (all other symbols as above), is Pyc/I. Thus, for a compressive longitudinal load, the maximum unit stress, pounds per square inch, is at the top of the beam and is

$$s = \frac{P}{A} + (M + Py)\frac{c}{I} \tag{18}$$

The unit tensile stress, pounds per square inch, at the bottom of the beam for the same load is

$$s = -\frac{P}{A} + (M + Py)\frac{c}{I} \tag{19}$$

Since the value of y depends on the total bending moment $(M + Py)$, and the bending moment depends in turn on the value of y, equations 18 and 19 are usually solved by a method of approximation. The value of y that would be caused by the cross-bending moment M, considered acting alone, is found first and is then used in the expression, $M + Py$. This new value of the total bending moment is used to find a closer approximation to y. This operation may be repeated as many times as desired. When the deflection is small, as in comparatively short beams, the value of y as found from the cross-bending moment above is often used without any further approximation.

Example. Find the stress at the bottom and at the top of a timber beam 6 in. wide, 8 in. deep, and 12 ft long, supported at each end, and carrying a distributed load of 400 lb per ft, and also an axial compressive load of 10,000 lb. The modulus of elasticity of the timber is 1,600,000.

Maximum unit stress will be at the center of the beam.

$$\frac{P}{A} = \frac{10{,}000}{48} = 208 \text{ lb per sq in.}$$

$$\frac{Mc}{I} = \frac{400 \times 12 \times 144}{8} \times \frac{6}{6 \times 8^2} = 1350 \text{ lb per sq in.}$$

See Tables I, III, pp. 5-22, 5-26, 5-28.

$$y = \frac{5 \times 4800 \times 144^3 \times 12}{384 \times 6 \times 8^3 \times 1{,}600{,}000} = 0.456 \text{ in.}$$

$$\frac{Pyc}{I} = \frac{10{,}000 \times .456 \times 6}{6 \times 8^2} = 71 \text{ lb per sq in.}$$

Total unit compressive stress (top) $= 208 + 1350 + 71 = 1629$ lb per sq in.

Total unit tensile stress (bottom) $= -208 + 1350 + 71 = 1213$ lb per sq in.

Here the stress due to deflection is small, as it usually will be in short deep beams.

COLUMNS

By Jasper O. Draffin

15. DEFINITIONS

A Column or Strut is a bar or structural member under axial compression, which has an unbraced length greater than about 8 or 10 times the least dimension of its cross-section. On account of its length, it is impossible to hold a column in a straight line under a load; a slight sidewise bending always occurs, causing flexural stresses in addition to the compressive stresses induced directly by the load. The lateral deflection will be in a direction perpendicular to that axis of the cross-section about which the moment of inertia is the least. Thus in Fig. 1*A* the column will bend in a direction perpendicular to *aa*; in Fig. 1*B* it will bend perpendicular to *aa* or *bb* and in Fig. 1*C* it is apt to bend in any direction.

The Radius of Gyration of a section with respect to an axis is equal to the square root of the quotient of the moment of inertia with respect to that axis divided by the area of the section, that is

$$k = \sqrt{\frac{I}{A}}; \quad \frac{I}{A} = k^2 \tag{1}$$

where I is the moment of inertia and A the sectional area. Unless otherwise mentioned, an axis through the center of gravity of the section is the axis considered. As in beams, the moment of inertia is an important factor in the ability of the column to resist bending, but for purposes of computation it is more convenient to use the radius of gyration.

The Length of a Column is the distance between points unsupported against lateral deflection.

Slenderness Ratio is the length l divided by the least radius of gyration k, both in inches. For steel, a *short column* is one in which l/k is less than about 20 or 30, and its failure under load is due mainly to direct compression; in a *medium length column*, l/k = about 30 to 175, and it will fail by a combination of direct compression and bending; in a *long column*, l/k is greater than about 175–200, and it will fail mainly by bending. For timber columns these ratios are about 0–30, 30–90, and above 90 respectively. The load which will cause a column to fail decreases as l/k increases. The above ratios apply to round-end columns. If the ends are fixed (see paragraph below), the effective slenderness ratio is one-half that for round-end columns, as the distance between the points of inflection is one-half the total length of the column. For flat ends it is intermediate between the two.

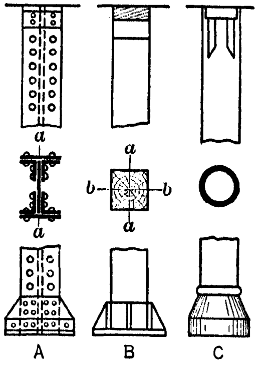

Fig. 1

Condition of Ends. As in beams, the conditions of the points of support have an important influence on the ability of the column to resist bending. The various conditions which may exist at the ends of columns are usually divided into four classes. Columns with round ends are such that at the bearing at either end there is perfect freedom of motion, as there would be with a ball-and-socket joint at each end. Columns with hinged ends are such as have perfect freedom of motion at the ends in one plane, as in compression members in bridge trusses where the loads are transmitted through end pins. Columns with flat ends have the bearing surface normal to the axis of the column and of sufficient area to give at least partial fixity to the ends of the columns against lateral deflection. Columns with fixed ends have the ends rigidly secured so that under any load the tangent to the elastic curve at the ends will be parallel to the axis in its original position.

Experiments prove that columns with fixed ends are stronger than columns with either flat, hinged, or round ends, and that columns with round ends are weaker than any of the other types. Columns with hinged ends are equivalent to those with round ends in the plane in which they have free movement; columns with flat ends have a value intermediate between those with fixed ends and those with round ends. It often happens that columns have one end fixed and one end hinged, or various other combinations. Their relative values may be taken as intermediate between those represented by the condition at either end. The extent to which the strength is increased by fixing the ends depends upon the length of the column, fixed ends having a greater effect on long columns than on short ones.

16. COLUMN FORMULAS

There is no exact theoretical formula which gives the strength of a column of any length under an axial load. Formulas involving the use of empirical coefficients have been deduced, however, and they give results which are consistent with the results of tests of full-sized members.

Euler's Formula. In 1757 Euler published his formula, which is based on the assumption that the failure of a column is due solely to the stresses induced by sidewise bending. This assumption is not true for very short columns, which fail mainly by direct compression, nor is it true for columns of medium length such as are usually needed in practice. The failure in such cases is by a combination of direct compression and bending. For columns having a ratio of slenderness greater than 200, Euler's formula is approximately correct and agrees closely with the results of tests.

Let P = axial load, pounds; l = length of column, inches; I = least moment of inertia, inches^4; k = least radius of gyration, inches; E = modulus of elasticity, pounds per square inch; and y = lateral deflection, inches, at any point along the column, that is caused by the load P. If a column has round ends, so that the bending is not restrained, the equation of its elastic curve is

$$EI\frac{dy^2}{dx^2} = -Py, \tag{2}$$

when the origin of the coordinate axes is at the top of the column, the positive direction of x being taken downwards and the positive direction of y in the direction of the deflection. Integrating the above expression twice and determining the constants of integration, there results

$$P = \Omega\pi^2\frac{EI}{l^2} \tag{3}$$

which is Euler's formula for long columns. The factor Ω is a constant depending on the condition of the ends. For round ends $\Omega = 1$; for fixed ends $\Omega = 4$; for one end round and the other fixed $\Omega = 2.05$. P is the load at which, if a slight deflection is produced, the column will not return to its original position; if P is decreased the column will approach its original position but if P is increased the deflection will increase until the column fails by bending.

For columns with value of l/k less than about 150, Euler's formula gives results distinctly higher than those observed in tests. Euler's formula is now little used except for long members and as a basis for the analysis of the stresses in some types of structural and machine parts. It always gives an *ultimate* and never an allowable load.

Secant Formula. The deflection of the column is used in the Euler formula, but if the load were truly axial it would be impossible to compute the deflection. If the column is assumed to have an initial eccentricity of load of e inches (see Seely, Resistance of Materials, 2nd Ed., p. 212, for suggested values of e), the equation for the deflection y becomes

$$y_{\max} = e\left(\sec\frac{l}{2}\sqrt{\frac{P}{EI}} - 1\right) \tag{4}$$

and the maximum unit compressive stress becomes

$$s = \frac{P}{A}\left(1 + \frac{ec}{k^2}\sec\frac{l}{2}\sqrt{\frac{P}{EI}}\right) \tag{5}$$

where l = length of column, inches; P = total load, pounds; A = area, square inches; I = moment of inertia, inches^4; k = radius of gyration, inches; c = distance from the neutral axis to the most compressed fiber, inches; E = modulus of elasticity, pounds per square inch; I and k are both taken with respect to the axis about which bending takes place. Because the formula contains the secant of the angle $(l/2\sqrt{P/EI})$ it is sometimes called the *secant formula*. It has been suggested by the committee on Steel-Column Research (*Trans.*, *A.S.C.E.*, 1933) that the best rational column formula can be constructed on the secant type, though of course it must contain experimental constants.

The secant formula can be used also for columns that are eccentrically loaded if e is taken as the actual eccentricity plus the assumed initial eccentricity.

Rankine's Formula is a modification of an earlier formula by Gordon, and is sometimes called "Gordon's Formula." It applies to columns of slenderness ratios of 20 to 200, which are usually required in practice. Rankine's formula is based on the assumption that the maximum unit stress s, pounds per square inch, occurs in the fiber most remote from the axis on the concave side of the deflected column, and is equal to the sum of the direct unit compressive stress and the unit compressive stress due to bending alone; that is, $s = (P/A) + s_1$ in which P is the load, pounds; A the sectional area, square inches; and s_1 the unit compressive stress due to bending, pounds per square inch. The value of s_1 in this equation may be expressed in terms of P by using the flexure formula, since the action is analogous to that of beams. Let l = the length of the column, inches; I = the least moment of inertia, inches^4; k = corresponding radius of gyration, inches; c = distance from axis to the remotest fiber on the concave side, inches; and y = lateral deflection of column, inches. Substituting in the flexure formula, $s_1 = Mc/I$, and by replacing M by its value Py and I by its value Ak^2, $s_1 = Pyc/(Ak^2)$. Hence the maximum unit compressive stress on the remotest fiber on the concave side is equal to $P/A + Pyc/(Ak^2)$. By analogy with the theory of beams the deflection y varies as l^2/c, so that by introducing an experimental coefficient ϕ, the expression for maximum unit stress may be written

$$s = \frac{P}{A} + \phi\left(\frac{Pl^2}{Ak^2}\right) = \frac{P}{A}\left[1 + \phi\left(\frac{l}{k}\right)^2\right] \tag{6}$$

which is Rankine's formula for the investigation of columns. Variations in the value of ϕ have been determined by many experiments on columns of different materials and different conditions of ends. The values in Table I are given in Merriman and have been used extensively in practice in the past. But present practice (1935) tends toward the use of the same constant for all end conditions, as tests show that for columns of the proportions in common use, variations in the material are more important than variations in end conditions.

Table I. Value of Coefficient ϕ in Rankine's Formula

Material	Both Ends Fixed	Fixed and Round	Both Ends Round
Timber	1/3000	1.95/3000	4/3000
Cast iron	1/5000	1.95/5000	4/5000
Wrought iron	1/36,000	1.95/36,000	4/36,000
Steel	1/25,000	1.95/25,000	4/25,000

The value to be taken for s in Rankine's formula is the ultimate compressive stress of the material for rupture, and the allowable compressive unit stress for design. Rankine's formula may be used in the investigation of an existing column by comparing the computed value of s with the proportional limit and with the ultimate strength of the material, thus determining the factor of safety. Similarly, the safe load P for an existing column may be computed by assuming an allowable unit stress s.

Ritter's Rational Constant. This is a theoretical value of ϕ such that it connects the curve for the Rankine formula with the curve for the Euler formula. Boyd's Strength of Materials gives its value as $\phi = s_u/(\pi^2 E)$, where s_u = ultimate compressive strength of material, pounds per square inch, and E = modulus of elasticity, pounds per square inch.

Straight-line Formula. The plotted results of actual tests on columns show that the relation between ultimate load and l/k is fairly well represented by a straight line, for columns which fail by flexure of the whole column and not by local collapse. For a value of $l/k = 0$, the average unit stress on the section, P/A, is equal to the ultimate in compression for brittle materials and to the yield point in compression for ductile materials. From the point thus determined the straight line representing the average results of tests is drawn tangent to the curve of Euler's formula for the material. The equation of the straight line is

$$\frac{P}{A} = s - C\frac{l}{k} \tag{7}$$

in which s is the unit stress at the ultimate in compression for a brittle material or at the yield point in compression for a ductile material, and C is a constant determined by experiment.

Table II gives average values of s and C for structural steel, cast iron, and wood. The loads given by the straight-line formula using the constants in this table are *ultimate loads*.

For purposes of design the straight-line formula is usually put in a form which gives allowable loads directly. Both the constant s and the constant C are divided by a factor of safety.

The straight-line formula is not suitable for investigating a column, that is, for determining the values of s due to given loads, because the term Cl/k is not a function of P/A. It may be used to find the safe load for a given column under a given unit stress, or to design a column for a given load and unit stress. From 1900 to 1930 the straight-line formula probably was used for designing more steel in America than the Rankine formula, but since 1930 the tendency has been towards the use of the Rankine type of formula See Table V, p. 5-42.

Table II. Ultimate Strength Constants for the Straight-line Column Formula— $P/A = s - Cl/k$

Material	s lb per sq in.	C			Limit of l/k		
		Round	Fixed	One end round One end fixed	Round	Fixed	One end round One end fixed
Structural steel......	35,000	150	75	100	160	320	240
Cast iron...........	34,000*	175	88	116	90	160	115
Wood..............	5,000*	40	20	30	75	150	112

* This is less than the ultimate in compression for small specimens of cast iron or wood, but from tests of full-size columns it seems to be the value to be used for full-size castings or timbers which may contain defects.

17. WOODEN COLUMNS

Wooden Column Formulas. One of the principal formulas is that formerly used by the A.R.E.A., $P/A = s_1(1 - l/60d)$, where P/A = allowable unit load, pounds per square inch; s_1 = allowable unit stress in direct compression on short blocks, pounds per square inch; l = length, inches; d = least dimension, inches. This formula is being replaced rapidly by formulas recommended by the A.S.T.M. and A.R.E.A. Committees of these societies, working with the U. S. Forest Products Laboratory, classified timber columns into three groups, as follows (A.S.T.M. Standards, 1933, D245–33):

1. Short Columns. The ratio of unsupported length to least dimension does not exceed 10. For these columns, the allowable unit stress should not be greater than the values given in Table V, p. 5–31, under compression parallel to the grain.

2. Intermediate-Length Columns. For columns the ratio of whose unsupported length to least dimension is greater than 10, the following formula, of the fourth power parabolic type, shall be used to determine the allowable unit stress until this allowable unit stress is equal to $^2/_3$ the allowable unit stress for short columns.

$$\frac{P}{A} = s_1\left[1 - \frac{1}{3}\left(\frac{l}{Kd}\right)^4\right] \tag{8}$$

where P = total load, pounds; A = area, square inches; s_1 = allowable unit compressive stress parallel to grain, pounds per square inch; see Table V, p. 5–31; l = unsupported length, inches; d = least dimension, inches. $K = l/d$ at the point of tangency of the parabolic and Euler curves, at which $P/A = (^2/_3)s_1$. The value of K for any species and grade is $(\pi/2)\sqrt{\frac{E}{6s_1}}$, where E = modulus of elasticity, pounds per square inch.

3. Long Columns. For columns in which P/A as computed by the formula above is less than $^2/_3\, s_1$, the following formula of the Euler type, which includes a factor of safety of 3, shall be used:

$$\frac{P}{A} = \frac{\pi^2}{36}\,\frac{E}{\left(\frac{l}{d}\right)^2} \tag{9}$$

Timber columns should be limited to a ratio of l/d equal to 50. No higher loads are allowed for square-ended columns. The strength of round columns may be considered the same as that of square columns of the same cross-sectional area.

Use of Timber Column Formulas. The values of E (modulus of elasticity) and s_1 (compression parallel to grain) to be used in the above formulas are given in Table V, p. 5–31. Table III gives the computed values of K for some common types of timbers. These may be substituted directly in the above formula for intermediate-length columns or may be used in conjunction with Table IV, which gives the strength of columns of intermediate length, expressed as a percentage of strength (s_1) of short columns. In the tables, the term " continuously dry " refers to interior construction where there is no excessive dampness or humidity; " occasionally wet but quickly dry " refers to bridges, trestles, bleachers and grandstands; " usually wet " refers to timber in contact with the earth or exposed to waves or tide-water.

18. STEEL COLUMNS

Types. Two general types of steel columns are in use: (1) rolled shapes; (2) built-up sections. The rolled shapes have had wide use since the introduction of wide-flanged

Table III. Values of *K* for Columns of Intermediate Length

NOTE: This table can also be used for columns not rectangular, the l/d being equivalent to $0.289l/k$, where k is the least radius of gyration of the section.

sections, especially since they may be obtained with large cross-sectional area. They are easily fabricated, accessible for painting, neat in appearance where they are not covered, and convenient in making connections. A disadvantage is the probability that thick sections are of lower-strength material than thin sections owing to the difficulty of adequately rolling the thick material. For the effect of thickness of material on yield point, see *Trans. A.S.C.E.*, vol. xcviii, p. 1377, 1933.

Guiding Principles in Design. The design of steel columns is always a cut-and-try method, as no law governs the relation between area and radius of gyration of the section. A column of given area is selected, and the amount of load that it will carry is computed by the proper formula. If the allowable load so computed is less than that to be carried, a larger column is selected and the load for it computed, the process being repeated until a proper section is found.

A few general principles should guide in proportioning columns. The radius of gyration should be approximately the same in the two directions at right angles to each other; the slenderness ratio of the separate parts of the column should not be greater than that of the column as a whole; the different parts should be adequately connected in order that the column may function as a single unit; the material should be distributed as far as possible from the center line in order to increase the radius of gyration.

Steel Column Formulas. Table V gives the more commonly used formulas. Table VI gives the maximum values for the slenderness ratio for steel columns as specified by various authorities.

Example. It is required to design a rolled-section steel column 24 ft long, to carry a load of 270,000 lb, using the formula of the Chicago Building Code, $P/A = 16{,}000 - 70l/k$.

For the first estimate, an area of about 27 sq in. will be used. From Table 64, Section 1, a 12 × 12-in. wide-flange section weighing 92 lb per ft, area of 27.06 sq in., a least radius of gyration of 3.08 in. will be selected.

$P = 27.06\,\{16{,}000 - (70 \times 24 \times 12/3.08)\} = 255{,}900$ lb.

This is too small. The next larger size, 99 lb per ft, has an area of 29.09 sq in., a radius of gyration of 3.09 in.

$P = 29.09\,\{16{,}000 - (70 \times 24 \times 12/3.09)\} = 275{,}700$ lb, which is satisfactory.

Table V. Steel Column Formulas

Organization Recommending or Using Formula	Formula,* Allowable Load, lb per sq in.
New York City Building Code, 1930 Pacific Coast Building Officials Conference Massachusetts Building Officials Conference Philadelphia Building Code, 1929 Wisconsin Building Code American Institute of Steel Construction, 1934	$\frac{P}{A} = \frac{18{,}000}{1 + \frac{l^2}{18{,}000k^2}}$ Maximum 15,000 except Mass. B.O.C., which is 13,500
American Bridge Company	$l/k = 0\text{–}60$; $P/A = 13{,}000$ $l/k = 60\text{–}120$; $P/A = 19{,}000 - 100l/k$ $l/k = 120\text{–}200$; $P/A = 13{,}000 - 50l/k$
American Railway Engineering Association	$l/k = 0\text{–}50$; $P/A = 12{,}500$ $l/k = 50\text{–}150$; $P/A = 15{,}000 - 50l/k$ $l/k =$ above 150; $P/A = 6.4E/(l/k)^2$
Recommended Building Code for Working Stresses in Building Materials, U. S. Bureau of Standards, 1926	Standard Steel † $P/A = 18{,}000 - 70l/k$ Maximum 14,000 Acceptable Steel † $P/A = 16{,}000 - 60l/k$
Chicago Building Code	$P/A = 16{,}000 - 70l/k$ Maximum 14,000
United States Bureau of Public Roads	Live Load: $\frac{P}{A} = \frac{16{,}000}{1 + \frac{l^2}{13{,}500k^2}}$ Dead Load: $\frac{P}{A} = \frac{24{,}000}{1 + \frac{l^2}{13{,}500k^2}}$ Maximum is that for $l/k = 40$

* In the formulas given, P = total load on column, pounds; A = cross-sectional area, square inches; l = length of column, inches; k = least radius of gyration, inches; E = modulus of elasticity, pounds per square inch.

† Standard steel is steel which satisfies the A.S.T.M. specifications for Structural Steel for Buildings, A.S.T.M. Standards, 1934, A 9–34. Acceptable steel is steel which is acceptable to the building officials but whose origin and properties have not been definitely determined.

* Average of two tests.

isting knowledge of steel columns. In 1913 the A.S.C.E., the A.R.E.A., and the U. S. Bureau of Standards cooperated in a test of columns. These columns were made to represent high-grade practice and covered a wide range of sections, both rolled shapes and built-up sections (*Trans. Am. Soc. C. E.*, vol. lxxxiii, 1919–1920).

The tests, summarized in Table VII showed that, for columns of the proportions commonly used, the effect of the variation in the steel, kinks, initial stresses, and similar defects in the column was more important than the effect of length. It also showed that the thin metal gave definitely higher strength, per unit area, than the thicker metal of the same type of section.

19. ECCENTRIC AND TRANSVERSE LOADS ON COMPRESSION MEMBERS

Eccentric Loads on Short Compression Members. Where a direct push acting on a member does not pass through the centroid but at a distance e, inches, from it, both direct and bending stresses are produced. For short compression members in which column action may be neglected, the direct unit stress is P/A, where P = total load, pounds, and A = area of cross-section, square inches. The bending unit stress is Mc/I where $M = Pe$ is the bending moment, pound-inches; c is the distance, inches, from the centroid to the fiber in which the stress is desired; I = moment of inertia, inches^4. The total unit stress at any point in the section is $s = P/A + Pec/I$, or $s = P/A(1 + ec/k^2)$, since $I = Ak^2$, where k = radius of gyration, inches.

Eccentric Loads on Columns. Various column formulas must be modified when the loads are not balanced, that is, when the resultant of the loads is not in line with the axis of the column. Let P be the load, pounds, applied at a distance e, inches, from the axis; the bending moment M is Pe. The maximum unit stress s, pounds per square inch, due to this bending moment alone, is $s = Mc/I = Pec/Ak^2$, where c = distance, inches, from the axis to the most remote fiber on the concave side; A = sectional area, square inches; k = radius of gyration in the direction of the bending, inches. This unit stress must be added to the unit stress induced if the resultant load were applied in line along the axis of the column. The modified formulas, expressed in allowable load per unit of area, are:

Modified Rankine's formula for eccentric loads (see p. 5–39):

$$\frac{P}{A} = \frac{s}{1 + \phi\left(\frac{l}{k}\right)^2 + \frac{ec}{k^2}} \tag{10}$$

Modified straight-line formula for eccentric loads (see p. 5–39):

$$\frac{P}{A} = \frac{s - \frac{Cl}{k}}{1 + \frac{ec}{k^2}} \tag{11}$$

The secant formula, see p. 5–38, can also be used for columns that are eccentrically loaded if the e in this formula is taken as the actual eccentricity plus the assumed initial eccentricity.

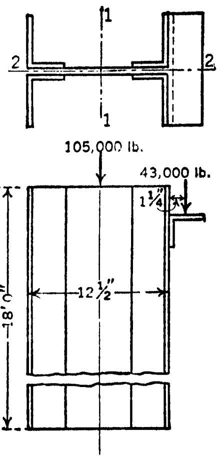

FIG. 2

Example. Design a steel column 18 ft long to carry an axial load of 105,000 lb and an additional load of 43,000 lb which comes from a crane runway, and which is 1 1/4 in. beyond the outside edge of the column.

The formula used will be the A.I.S.C. formula, $P/A = 18{,}000/\{1 + (l^2/18{,}000k^2)\}$, and the shape selected will be a plate and four angles, as shown in Fig. 2.

Using 10,000 lb per sq in. as a preliminary estimate for the first selection, one plate $12 \times 5/16$ in. and four angles $5 \times 3\ 1/2 \times 3/8$ in. will have an area of 15.95 sq in. The safe load for this column will now be found. The moment of inertia I_{1-1} is 412 in.^{4}, the radius of gyration k_{1-1} is 5.08 in., and the radius of gyration k_{2-2} is 2.08 in.

Considering the safe load with respect to axis 2–2 about which neither load is eccentric,

$$P = \frac{15.95 \times 18{,}000}{1 + \frac{(18 \times 12)^2}{18{,}000 \times (2.08)^2}} = 179{,}400 \text{ lb}$$

Consider now the safe load about axis 1–1, with respect to which the load of 105,000 lb is axial, and the load of 43,000 lb has an eccentricity of 7 1/2 in. The load of 43,000 lb will produce a stress due to its eccentricity, and this stress will reduce by that amount the unit load that the column can carry. The safe load will therefore be

$$P = 15.95\left(\frac{18{,}000}{1 + \frac{(18 \times 12)^2}{18{,}000 \times (5.08)^2}} - \frac{43{,}000 \times 7.5 \times 6.25}{412}\right) = 183{,}000 \text{ lb}$$

The area exceeds that needed by about 3 sq in.; the next smaller size is one plate $12 \times 5/16$ in and four angles $5 \times 3\ 1/2 \times 5/16$ in. The area is 13.99 sq in., moment of inertia, $I_{1-1} = 356$ in.^{4} $k_{1-1} = 5.04$ in., and $k_{2-2} = 2.03$ in. With respect to the axis 2–2

$$P = \frac{13.99 \times 18{,}000}{1 + \frac{(18 \times 12)^2}{18{,}000 \times (2.03)^2}} = 154{,}600 \text{ lb}$$

With respect to axis 1–1,

$$P = 13.99\left(\frac{18{,}000}{1 + \frac{(18 \times 12)^2}{18{,}000 \times (5.04)^2}} - \frac{43{,}000 \times 7.5 \times 6.25}{356}\right) = 149{,}300 \text{ lb}$$

As the load to be carried is 148,000 lb this column is satisfactory.

Column Subjected to Transverse or Cross-bending Loads. (See Seely, Resistance of Materials, 1st Ed., p. 247.) A compression member that is subjected to cross-bending loads may be considered to be (1) a beam subjected to end thrust as discussed on p. 5–35 or (2) a column subjected to cross-bending loads, depending on the relative magnitude of the end thrust and cross-bending loads, and on the dimensions of the member. The various column formulas may be modified so as to include the effect of cross-bending loads. In this form they are:

Modified Rankine's Formula for transverse loads:

$$s = \frac{P}{A}\left(1 + \phi\frac{l^2}{k^2}\right) + \frac{Pyc}{Ak^2} + \frac{Mc}{Ak^2} \tag{12}$$

Modified straight-line formula for transverse loads:

$$\frac{P}{A} = \left(s - \frac{Cl}{k}\right) - \frac{Pyc}{Ak^2} - \frac{Mc}{Ak^2} \qquad (13)$$

Modified secant formula for transverse loads:

$$= \frac{P}{A}\left(1 + (e + y) \qquad \left(\frac{l}{2k}\right)\sqrt{\frac{P}{AE}} + \frac{Mc}{Ak^2} \qquad (14)$$

In these formulas, s is the maximum unit stress on the concave side, pounds per square inch; P = the axial end load, pounds; A = cross-sectional area, square inches; M = moment due to cross-bending load, pound-inches; y = deflection due to cross-bending load, inches; k = radius of gyration, inches; l = length of column, inches; e = assumed initial eccentricity, inches; c = distance, inches, from the axis to the most remote fiber on the concave side; C = experimental constant (see p. 5–40). The modified straight-line formula, like the straight-line formula, cannot be used to solve for s (see p. 5–45).

20. CAST-IRON COLUMNS

Disadvantages of Cast-iron Columns. Tests made on cast-iron columns show that a large factor of safety should be used when the material is employed in column construction. It is difficult to obtain a practical formula for the strength of a cast-iron column on account of the uncertainty of the quality of the casting, and the danger of hidden defects such as internal stresses due to unequal cooling of the casting, cinder or dirt, blowholes, cold shuts and cracks on the inner surface, which cannot be discovered by external inspection. Variation in the thickness of the wall due to shifting of the core is another common defect. Brackets which are usually cast on the face of the column to support beams and girders may fail by shearing unless most skillfully designed.

Tests of full-size cast-iron columns made at the Watertown Arsenal and at Phoenixville, Pa.. showed that for short columns the strength in compression is much less than

Table VIII. Allowable Safe Loads on Round Cast-Iron Columns, in Thousands of Pounds

the strength of small test specimens of cast iron. For short columns, failure of test columns takes place by shearing on an inclined plane; for long columns, failure takes place by rupture on the convex side. Failure of cast-iron columns is always a sudden, shattering failure.

Advantages of Cast-iron Columns. For buildings of moderate height cast-iron columns are sometimes used instead of wooden columns to save space, and instead of steel columns to save expense. The fact that they are cheap and can be obtained more quickly than steel built-up columns will prevent them from being superseded entirely. Moreover they can be cast in almost any desired shape with lugs and brackets attached for supporting beams or girders.

Design of Cast-iron Columns. Cast-iron columns are usually in the form of a hollow cylinder, as this is the most economical and reliable type to use. Hollow rectangular sections are permitted by some building codes and are convenient to use in outer walls where it is necessary to bond into the masonry. They are less reliable than the hollow round type and should be used only when it is impossible to use anything else.

The design will usually be governed by building laws, and the following limitations which are usually specified, should be adhered to: Minimum thickness of wall, $^1/_2$ to $^3/_4$ in.; minimum diameter of column, 6 in.; maximum length, 20 × diameter or 70 × least radius of gyration. When it becomes necessary to use a wall thickness greater than 2 in. or a diameter over 18 in. it will be cheaper and more satisfactory to abandon cast iron and substitute a steel column. Within the above limitations the ratio of length to radius of gyration should be made as small as possible; that is, if a choice may be made of two columns of equal sectional area but of different diameter and, therefore, different wall thicknesses, the one with the larger diameter will be the stronger.

The safe load on a cast-iron column as given by the building law of the City of New York is $P/A = 9000 - 40\,(l/k)$, where P = the safe load, pounds; A = area of section, square inches; l = length, inches; k = least radius of gyration. Tables VIII and IX give the safe loads for cast-iron columns according to this formula.

Table IX. Allowable Safe Loads on Square Cast-iron Columns, in Thousands of Pounds

SHAFTS

By Jasper O. Draffin

21. DEFINITIONS

Torsional Stress. A bar is under torsional stress when it is held fast at one end and a force acts at the other end to twist the bar. In a round bar, Fig. 1, with a constant force acting, the straight line *a–b* becomes the helix *ad*, and a radial line in the cross-section, *ob*, moves to the position *od*. The angle *bad* remains constant while the angle *bod* increases with the length of the bar. Each cross-section of the bar tends to shear off the one adjacent to it, and in any cross-section the shearing stress at any point is normal to a radial line drawn through the point. Within the shearing proportional limit a radial line of the cross-section remains straight after the twisting force has been applied, and the unit shearing stress at any point is proportional to its distance from the axis.

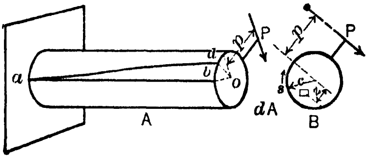

FIG. 1

The Twisting Moment, T, is equal to the product of the resultant, P, of the twisting forces, and its distance from the axis, p.

The Resisting Moment, T_r, in torsion, is equal to the sum of the moments of the unit shearing stresses acting along a cross-section with respect to the axis of the bar. If dA is an elementary area of the section at a distance of z units from the axis of a circular shaft (Fig. 1B), and c is the distance from the axis to the outside of the cross-section where the unit shearing stress is s, then the total shearing force acting on dA is $(sz/c)dA$, its moment with respect to the axis is $(sz^2/c)dA$, and the sum of all the moments of the unit shearing stresses on the cross-section is $\int (sz^2/c)\, dA$. In this expression the factor $\int z^2 dA$ is the polar moment of inertia of the section with respect to the axis. Denoting this by J, the resisting moment may be written sJ/c.

The Polar Moment of Inertia of a surface about an axis through its center of gravity and perpendicular to the surface is the sum of the products obtained by multiplying each elementary area by the square of its distance from the center of gravity of its surface; it is equal to the sum of the moments of inertia taken with respect to two axes in the plane of the surface at right angles to each other passing through the center of gravity. It is represented by J, inches^4. For the cross-section of a round shaft,

$$J = (1/32)(\pi d^4), \quad \text{or} \quad 1/2\pi r^4 \tag{1}$$

for a hollow shaft

$$J = (1/32)\,[\pi(d^4 - d_1^4)] \tag{2}$$

where d is the outside and d_1 the inside diameter, in inches, or

$$J = 1/2\,[\pi(r^4 - r_1^4)] \tag{3}$$

where r is the outside and r_1 the inside radius, in inches.

The Polar Radius of Gyration, k_p, is also sometimes used in formulas; it is defined as the radius of a circumference along which the entire area of a surface might be concentrated and have the same polar moment of inertia as the distributed area. For a solid circular section,

$$k^2_p = (1/8)d^2 \tag{4}$$

for a hollow circular section,

$$k^2_p = (1/8)(d^2 + d_1^2) \tag{5}$$

22. DETERMINATION OF TORSIONAL STRESSES

The Torsion Formula for Round Shafts. The conditions of equilibrium require that the twisting moment, T, be opposed by an equal resisting moment, T_r, so that for the values of the maximum unit shearing stress, s_s, within the proportional limit, the torsion formula for round shafts becomes

$$T_r = T = \frac{s_s J}{c} \tag{6}$$

If s_s is in pounds per square inch, then T_r and T must be in pound-inches, J is in inches^4 and c in inches. For solid round shafts having a diameter, d, inches,

$$J = \frac{1}{32}\pi d^4 \quad \text{and} \quad c = \frac{1}{2}d \tag{7}$$

and

$$T = \frac{1}{16}\pi d^3 s_s \quad \text{or} \quad s_s = \frac{16T}{\pi d^3} \tag{8}$$

For hollow round shafts

$$J = \frac{\pi(d^4 - d_1^4)}{32}, \quad c = \frac{1}{2}d \tag{9}$$

and the formula becomes

$$T = \frac{s_s \pi(d^4 - d_1^4)}{16d} \quad \text{or} \quad s_s = \frac{16Td}{\pi(d^4 - d_1^4)} \tag{10}$$

It should be remembered that the torsion formula applies only to solid circular shafts or hollow circular shafts and then only when the load is applied in a plane perpendicular to the axis of the shaft and when the shearing proportional limit of the material is not exceeded.

Shearing Stress in Terms of Horsepower. If the shaft is to be used for the transmission of power, the value of T, pound-inches, in the above formulas becomes 63,030 H/n, where H is the horsepower to be transmitted and n = r.p.m. The maximum unit shearing stress, pounds per square inch, then, is:

$$\text{For solid round shafts: } s_s = \frac{321{,}000\,H}{nd^3} \tag{11}$$

$$\text{For hollow round shafts: } s_s = \frac{321{,}000\,Hd}{n(d^4 - d_1^4)} \tag{12}$$

If s_s is taken as the allowable unit shearing stress, the diameter, d, inches, necessary to transmit a given horsepower at a given shaft speed can then be determined. It should be remembered, however, that these formulas give the stress due to torsion only, and allowance must be made for any other loads such as the weight of the shaft and pulleys, and tension in belts.

Angle of Twist. When the unit shearing stress s_s does not exceed the proportional limit the angle *bod* (Fig. 1) for a solid round shaft may be computed from the formula:

$$\theta = \frac{Tl}{E_s J} \tag{13}$$

where θ = angle, expressed in radians; l = length of shaft, inches; E_s = shearing modulus of elasticity of the material, pounds per square inch; T = twisting moment, pound-inches. Values of E_s for different materials are: steel, 12,000,000; wrought iron, 10,000,000; and cast iron, 6,000,000.

When the angle of twist on a section begins to increase in a greater ratio than the twisting moment, it may be assumed that the shearing stress on the outside of the section has reached the proportional limit. The shearing stress at this point may be determined by substituting the twisting moment at this instant in the torsion formula.

Torsion of Non-circular Cross-sections. The analysis of shearing stress distribution along non-circular cross-sections of bars under torsion is complex. By drawing two lines at right angles through the center of gravity of a section before twisting, and observing the angular distortion after twisting, it has been found from many experiments that in non-circular sections the shearing unit stresses are not proportional to their distances from the axis. Thus in a rectangular bar there is no shearing stress at the corners of the sections and the stress at the middle of the wide side is greater than at the middle of the narrow side. In an elliptical bar the shearing stress is greater along the flat side than at the round side.

It has been found by tests (Bach, *Elastizität u. Festigkeit*; and Young, *Bull.* 4, *School of Eng. Research*, Univ. of Toronto) as well as by mathematical analysis that the torsional resistance of a section made up of a number of rectangular parts is approximately equal to the sum of the resistances of the separate parts. It is on this basis that nearly all the formulas for non-circular sections have been developed. For example, the torsional resistance of an I-beam is approximately equal to the sum of the torsional resistances of the web and the outstanding flanges. In an I-beam in torsion the maximum shearing stress will occur at the middle of the side of the web, except where the flanges are thicker than the web, and then the maximum stress will be at the midpoint of the width of the flange. Re-entrant angles, as those in I-beams and channels, are always a source of weakness in members subjected to torsion. Table I gives approximate values of the maximum unit shearing stress s_s and the angle of twist θ induced by twisting bars

Table I. Approximate Formulas for Maximum Shearing Stress and Angle of Twist in Members Subjected to Torsion

(From Seely's Advanced Mechanics of Materials)

s_s = shearing unit stress, pounds per square inch; T = twisting moment, pound-inches; θ = angle of twist, radians, in length, l, inches; J = polar moment of inertia, inches^4; E_s = shearing modulus of elasticity, pounds per square inch; A = area of cross-section, square inches; y = distance of most remote edge from center of bar, inches. Tests of brittle metal are those made by Bach, *Elastizität u. Festigkeit*, 1924, except for those marked *, which are by Kommers, *Amer. Mach.*, vol. xl, p. 941, 1914.

of various cross-sections, it being assumed that s_s is not greater than the proportional limit and that the modulus of elasticity, E_s, remains a constant.

Ultimate Strength in Torsion. In a torsion failure, the outer fibers of a section are the first to shear and the rupture extends toward the axis as the twisting is continued. The torsion formula for round shafts has no theoretical basis after the shearing stresses on the outer fibers exceed the proportional limit, as then the stresses along the section are no longer proportional to their distances from the axis. It is convenient, however, to compare the torsional strength of various materials by using the formula to compute values of s_s at which rupture takes place. These computed values of the maximum stress sustained before rupture are somewhat higher for iron and steel than the ultimate strength of the materials in direct shear. Computed values of the ultimate strength in torsion are found by experiment to be as follows: cast iron, 30,000 lb per sq in.; wrought iron, 55,000 lb per sq in.; medium steel, 65,000 lb per sq in.; timber, 2000 lb per sq in. These computed values of twisting strength may be used in the torsion formula to determine the probable twisting moment that will cause rupture of a given round bar or to determine the size of a bar that will be ruptured by a given twisting moment. In design, large factors of safety should be taken, especially when the stress is reversed as in reversing engines and when the torsional stress is combined with other stresses as in shafting.

Effect of Keyway in Shaft. The sharp re-entrant angles in keyways produce high local stresses at these points. Based on studies made by hydrodynamical and soap-film methods, the local stress in the corner has been determined as equal to the stress in a similar shaft without a keyway, multiplied by a constant, K, which depends on the radius of the corner. The constants are approximately:

Radius of corner, in.	0.1	0.2	0.3	0.4	0.5	0.6	0.7
K	5.4	3.4	2.7	2.3	2.1	2.0	1.9

Under steady loading these high stresses are probably not very important, as a ductile material allows an adjustment to take place, but if the shaft is subjected to repeated loads a crack may start at the corner.

Experiments by Moore (*Bull.* 42, Eng. Exp. Sta., Univ. of Ill., 1909) on shafts from 1 1/4 to 2 1/4 in. in diameter showed that keyways reduced the elastic strength and the stiffness but did not reduce the ultimate strength. If E' = ratio of strength at the proportional limit of a shaft with a keyway to strength at the proportional limit of a shaft without a keyway, N = ratio of the angle of twist of a shaft with a keyway to that of a shaft without a keyway, w = width of keyway divided by diameter of shaft, and h = depth of keyway divided by diameter of shaft, the ratios obtained were: $E' = 1.0 - 0.2w - 1.1h$; $N = 1.0 + 0.4w + 0.7h$, for ranges of w from 0.25 to 0.50, and of h from 0.125 to 0.1875.

CYLINDERS, PLATES, ROLLERS AND RIVETED JOINTS

By Jasper O. Draffin

23. CYLINDERS

Thin Cylinders under Internal Pressure. A cylinder is regarded as thin when the thickness of the wall is small compared with the diameter. It is assumed that in such cases the tensile stress across a longitudinal section is uniformly distributed over the thickness of the wall. If p = internal pressure, pounds per square inch; l = length of cylinder, inches; t = thickness of wall, inches; d = diameter of cylinder, inches; and s = tensile stress, pounds per square inch:

$$pdl = 2\,stl \quad \text{or} \quad s = \frac{pd}{2t} \tag{1}$$

For tensile stress across a transverse section

$$\frac{p\pi d^2}{4} = st\pi d \quad \text{or} \quad s = \frac{pd}{4t} \tag{2}$$

Formula 2 applies also to the stresses in the walls of a thin hollow sphere, hemisphere, or dome. This analysis does not apply where holes are cut in the cylinder for rivets or for other purposes. Where holes are cut, the tensile stresses must be found by the method used in riveted joints. (See Art. 26.)

Thin Cylinders under External Pressure. It is difficult to derive a rational formula for the stresses in a thin cylinder under external pressure since failure occurs partly by collapse and this is greatly influenced by any slight ellipticity. Tests made by Professor R. T. Stewart (*Trans. A.S.M.E.*, vol. xxvii, p. 730) on lap-welded steel tubes showed that the length was not important provided it was not over 6 times the diameter. For ratios of t/d less than 0.023

$$p = 1000\left[1 - \sqrt{1 - 1600\left(\frac{t^2}{d^2}\right)}\right] \tag{3}$$

where p = collapsing pressure, pounds per square inch; t = thickness of wall, inches; and d = diameter of tube, inches. For ratios of t/d greater than 0.023

$$p = 86{,}670\left(\frac{t}{d}\right) - 1386 \tag{4}$$

Professor A. P. Carmen made tests (*Bull.* 5, *Eng. Exp. Sta.*, Univ. of Ill., 1906) and found, with ratios of t/d less than 0.025, for cold-drawn seamless steel tubes,

$$p = 50{,}200{,}000\left(\frac{t}{d}\right) \tag{5}$$

and for seamless brass tubes

$$p = 25{,}150{,}000\left(\frac{t}{d}\right)^3 \tag{6}$$

For an extended discussion see Strength of Thin Cylindrical Shells under External Pressure by Saunders and Windenburg, and The Collapsing Strength of Steel Tubes by Jasper and Sullivan (*Trans. A.S.M.E.*, Applied Mechanics, September–December, 1931, pp. 207–245).

Thick Cylinders. Timoshenko and Lessells (Applied Elasticity) and Swain (Strength of Materials) give the following formulas for the stresses in thick hollow cylinders under internal and external pressure. Under internal pressure only, the maximum tensile stress s_t in a tangential direction on the inner surface is

$$s_t = p\frac{(a^2 + b^2)}{(b^2 - a^2)} \tag{7}$$

where p = internal pressure, pounds per square inch; a = inside radius and b = outside radius, inches; under internal pressure the maximum compressive stress in a radial direction is on the inside and equals p, pounds per square inch.

When the cylinder is subjected to an external pressure p the maximum compressive unit stress will be at the inner surface and is

$$s_c = \frac{2\,pb^2}{b^2 - a^2} \tag{8}$$

In *shrinkage fits* a hollow cylinder or collar is forced over a cylinder or shaft having an outer diameter slightly greater than the inside diameter of the outer cylinder. This will cause compressive stresses in the inner cylinder and tensile stresses in the outer cylinder. This method is sometimes used in the manufacture of guns. Timoshenko and Lessells (Applied Elasticity) give the equation for the pressure p, pounds per square inch, between the two cylinders as

$$p = \frac{E\delta}{b}\,\frac{(b^2 - a^2)(c^2 - b^2)}{2b^2(c^2 - a^2)} \tag{9}$$

where E = modulus of elasticity, a = inner radius of inner cylinder, b = outer radius of inner cylinder, c = outer radius of outer cylinder, δ = amount by which the outer radius of the inner cylinder exceeds the inner radius of the outer cylinder. With the pressures known, external pressure on the inner cylinder and internal pressure on the outer cylinder, the stresses can be computed by means of equations 7 and 8.

A comparison of the various theories of failure of thick cylinders is given in Seely's Advanced Mechanics of Materials from which the following is abstracted:

For brittle materials, as cast iron, the *maximum stress theory* is recommended. For internal pressure only it gives

$$t = r_1\left[\sqrt{\frac{s_w + p}{s_w - p}} - 1\right] \tag{10}$$

For external pressure only it gives

$$t = r_1\left[\sqrt{\frac{s_w}{2p + s_w}} - 1\right] \tag{11}$$

For ductile materials the maximum strain theory is recommended. It is used by the United States Government for the design of guns. For internal pressure only it gives

$$t = r_1\left[\sqrt{\frac{E\epsilon_w + (1 - m)p}{E\epsilon_w - (1 + m)p}} - 1\right] \tag{12}$$

and for external pressure only

$$t = r_1\left[\sqrt{\frac{E\epsilon_w}{E\epsilon_w - 2p}} - 1\right] \tag{13}$$

where t = thickness, inches; s_w = allowable working unit stress, pounds per square inch; p = pressure, internal or external, pounds per square inch; r_1 is the inner radius of cylinder, inches; E = modulus of elasticity; m = Poisson's ratio; ϵ_w = allowable working unit deformation of the material.

24. PLATES

Circular Flat Plates. Table I gives equations for deflection and stresses in circular plates based mainly on the theoretical analyses developed by Grashof. (See Morley's Strength of Materials; Seely's Advanced Mechanics of Materials; Timoshenko and Lessells' Applied Elasticity.) Experience shows that the strength of flat plates is greater than is indicated by these equations.

Elliptical Flat Plates. An approximate formula for the maximum stress s in elliptical plates, simply supported at the edge, having a major axis $2a$, a minor axis $2b$, a thickness t, and carrying a distributed load of w pounds per square inch, is

$$s = \frac{(3a - 2b)}{a}\,\frac{wb^2}{t^2} \tag{14}$$

Table I. Maximum Stresses and Deflection for Circular Flat Plates

m = Poisson's ratio; P = concentrated load, pounds; w = distributed load, pounds per square inch; r = radius of plate, inches; t = thickness of plate, inches; E = modulus of elasticity.

Type of Load and Support	Maximum Stress at Edge	Maximum Stress at Center	Maximum Deflection at Center, $m = 1/3$
Uniform load, edge simply supported		$\frac{3}{8}\frac{wr^2}{t^2}(3+m)$	$\frac{2}{3}\frac{wr^4}{Et^3}$
Uniform load, edge fixed	Radial direction $\frac{3}{4}\frac{wr^2}{t^2}$ Tangential direction $\frac{3}{4}\frac{wmr^2}{t^2}$	$\frac{3}{8}\frac{wr^2}{t^2}(1+m)$	$\frac{1}{6}\frac{wr^4}{Et^3}$
Concentrated load at center, edge supported		Infinite	$\frac{5}{3}\frac{Pr^2}{\pi Et^3}$
Concentrated load at center, edge fixed	Radial direction $\frac{3P}{2\pi t^2}$ Tangential direction $\frac{3}{2}\frac{Pm}{\pi t^2}$	Infinite	$\frac{2}{3}\frac{Pr^2}{\pi Et^3}$
Uniform load, supported on central area of radius r_0		$\frac{3}{2}\frac{wr^2}{t^2}\left[(1+m)\log_e\frac{r}{r_0} + \frac{1}{4}(1-m)\left(1-\frac{r_0^2}{r^2}\right)\right]$	$\frac{3}{16}(1-m)(7+3m)\frac{wr^4}{Et^3}$
Load on central area of radius r_0, edge simply supported		$\frac{3(1+m)P}{2\pi t^2}\left[\frac{1}{m+1} + \log_e\frac{r}{r_0} - \left(\frac{1-m}{1+m}\right)\frac{r_0^2}{4r^2}\right]$	$\frac{5}{3}\frac{Pr^2}{\pi Et^3}$
Load on central area of radius r_0, edge fixed		$\frac{3(1+m)P}{2\pi t^2}\left(\log_e\frac{r}{r_0} + \frac{r_0^2}{4r^2}\right)$ r must be $> 1.7\, r_0$	$\frac{2}{3}\frac{Pr^2}{\pi Et^3}$

Square Flat Plates. Where the load is w pounds per square inch and the plate is supported on the four edges, each b inches long, the maximum moment and maximum stress will be along a diagonal. The moment M per unit length of diagonal will be $wb^2/24$, and the unit stress will be

$$s = \frac{wb^2}{4t^2} \tag{15}$$

where t = thickness, inches.

With edges fixed and load distributed the maximum stress at the center of each of the edges is, approximately, $s = 0.20\, wb^2/t^2$. Nichols found in experiments with steel plates a value of

$$s = 0.141\frac{wb^2}{t^2} \tag{16}$$

and Bach found

$$s = 0.19\frac{wb^2}{t^2} \tag{17}$$

Rectangular Flat Plates. For a distributed load w pounds per square inch, with supports along the four sides, and assuming a uniform distribution of moment along a diagonal, Seely gives (Advanced Mechanics of Materials, p. 141) the stress as

$$s = \frac{a^2b^2w}{2t^2(a^2+b^2)} \tag{18}$$

in which a is the length of the long side and b the length of the short side.

For rectangular plates fixed along the four sides, for ductile materials, Bach found experimentally that the coefficient K in the moment equation $M = Kwb^2$ was such that the moment along the fixed edge and along the center was about the same, and that the values of K (see Seely, Advanced Mechanics of Materials, p. 144) for different ratios of the length of the sides a and b were about as follows:

$b/a =$	0	0.2	0.4	0.6	0.8	1.0
$K =$	0.63	0.62	0.56	0.48	0.40	0.32

Timoshenko and Lessells (Applied Elasticity) give an analysis which shows that the maximum moment at the center of the plate in strips of unit width through the center of the plate, parallel to the long and short sides respectively, when the sides are simply supported, and the load is w pounds per square inch uniformly distributed over the plate, is given by the equations

$$M_{1\,\max} = K_1\,wb^2 \tag{19a}$$

and

$$M_{2\,\max} = K_2\,wb^2 \tag{19b}$$

the approximate deflection y is given by

$$y_{\max} = \frac{Dwb^4}{Et^3} \tag{20}$$

where t = thickness, inches; E = modulus of elasticity; K_1, K_2, and D are constants given in Table II.

Table II. Values of Constants D, K_1 and K_2 for Rectangular Plates with Supported Edges and Uniformly Distributed Loads

a = long side, b = short side, Poisson's ratio = 0.3.

a/b	D	K_1	K_2	a/b	D	K_1	K_2

1.6	.0906	.0862	.0493	∞	.1422	.1250	.0375
1.7	.0964	.0908	.0486				

For rectangular plates with the edges fixed, the maximum deflection is given by the same equation as for the plates with supported edges, but with the constant D given in Table III. The maximum bending moment in a strip of unit width is at the middle of the longer fixed side and is equal to $M_{\max} = Kwb^2$, K is given in Table III, and a and b are the lengths of the long and short sides respectively.

Professor Westergaard in a study of reinforced-concrete slabs supported on columns has computed the moments in medium-thick rectangular and elliptical plates (*Proc. A.C.I.*, 1921). These are plates in which there is neither an appreciable absorption of energy by the vertical shearing stresses nor by the stretching of the middle plane of the plate. By means of a number of simplifying assumptions the values for the moments as given in Table IV were found.

Table III. Values of Constants D and K for Rectangular Plates with Fixed Edges and a Uniformly Distributed Load

Poisson's ratio = 0.3

a/b	1.00	1.25	1.50	1.75	2.00	∞
D	0.0138	0.0199	0.0240	0.0264	0.0277	0.0284
K	0.0513	0.0665	0.0757	0.0817	0.0829	0.0833

25. STRESSES IN SOLIDS UNDER PRESSURE

Cylindrical and Spherical Rollers. Approximate equations for areas of contact and pressures have been worked out for a number of cases (Timoshenko and Lessells' Applied Elasticity). These are given in Table V.

Hertz Equations. A general mathematical solution of the problem of the stresses produced by the pressure of one solid upon another, of which cylindrical and spherical rollers are a special case, was made by H. Hertz (English translation in Miscellaneous Papers by H. Hertz). The Hertz equations are very complex and deal only with surface stresses. Thomas and Hoersch (*Bull.* 212, *Eng. Exp. Sta.*, University of Illinois, 1930), as a part of an investigation of railroad rails and the development of transverse fissures in them, extended the Hertz equations to a study of the shearing stresses within the

Table IV. Formulas for Bending Moments in Rectangular Flat Slabs

Values are per unit width. Poisson's ratio = 0, a = longer side, b = shorter side, $\alpha = b/a$.

		Moments in Span b		Moments in Span a	
		At center of edge	At center of slab	At center of edge	At center of slab
Rectangular Slabs	Four edges simply supported	0	$\frac{1/8\, wb^2}{1 + 2\alpha^3}$	0	$\frac{wb^2}{48}(1 + \alpha^2)$
	Span b fixed; span a simply supported	$\frac{1/12\, wb^2}{1 + 0.2\,\alpha^4}$	$\frac{1/24\, wb^2}{1 + 0.4\,\alpha^4}$	0	$\frac{wb^2}{80}(1 + 0.3\,\alpha^2)$
	Span a fixed; span b simply supported	0	$\frac{1/8\, wb^2}{1 + 0.8\,\alpha^2 + 6\alpha^4}$	$\frac{1/8\, wb^2}{1 + 0.8\,\alpha^4}$	$0.015\, wb^2 \left(\frac{1 + 3\alpha^2}{1 + \alpha^4}\right)$
	All edges fixed	$\frac{1/12\, wb^2}{1 + \alpha^4}$	$\frac{1/8\, wb^2}{3 + 4\alpha^4}$	$1/24\, wb^2$	$0.009\, wb^2(1+2\alpha^2-\alpha^4)$
Elliptical slab with fixed edges; diameters a and b; $b/a = \alpha$		$\frac{1/12\, wb^2}{1 + 2/3\,\alpha^2 + \alpha^4}$	$\frac{1/24\, wb^2}{1 + 2/3\,\alpha^2 + \alpha^4}$	$\frac{1/12\, wb^2\,\alpha^2}{1 + 2/3\,\alpha^2 + \alpha^4}$	$\frac{1/24\, wb^2\,\alpha^2}{1 + 2/3\,\alpha^2 + \alpha^4}$

solid. They developed methods, too long to be given here, of computing the magnitude and location of the maximum shearing stresses produced in solids under pressure, such as in railroad rails under a wheel load. They have obtained experimental verification of the correctness of their equations by a " strain-etch " method, but point out that the mathematical equations derived do not hold except for thick material and where the ratio of the length of contact to the width of contact is large.

In a cylinder of radius R, inches, under a load P', pounds per inch of length, on a plane, assuming Poisson's ratio as $1/4$ the maximum shearing unit stress $s_s = 677 \sqrt{P'/R}$, the width of contact equals $0.000564 \sqrt{P'R}$, the depth to the point of maximum shear is $0.000222 \sqrt{P'R}$, and the maximum intensity of pressure is $2256 \sqrt{P'/R}$. In the case of crossed cylinders, the empirical equation is

$$s_s = \frac{11{,}750\, P^{1/3}}{\left(\frac{R_1}{R_2}\right)^{0.271} R_2^{2/3}} \tag{21}$$

where R_1 = radius of larger cylinder; R_2 = radius of smaller cylinder; P = total pressure, pounds, between the two solids; the ratio R_1/R_2 is only true within the limits of 1 and 8. Table VI gives a number of values computed by the methods of Thomas and Hoersch.

Stribeck made extensive experiments on ball bearings in 1898–1900, and his reports are translated in *Trans. A.S.M.E.*, vol. xxix, p. 421.

Where rollers are moving, as at the end of a truss or girder or with a rolling lift bridge, under relatively high pressures, the plate on which the roller rests is the critical part. The metal of the plate tends to flow longitudinally under the backward and forward motion. Wilson (*Bull.* 191, *Eng. Exp. Sta.*, University of Illinois, 1929) reports on experiments with rollers of the size used in rolling lift bridges, between 116 in. and 476 in. radius, and concludes that the bearing capacity of a plate depends upon its thickness, the tensile strength of the material, and the diameter of the roller. He proposes the formula

$$P = (12{,}000 + 80\,D)\left(\frac{p - 13{,}000}{23{,}000}\right)$$

where P = safe working load, pounds per inch width of plate; D = diameter of the roller, inches; p = yielding point strength of the material in tension, pound per square inch. The thickness of the plate, inches, should not be less than $(1.0 - 0.004\,D)$ with D not less than 120 in. Steel bridges usually have one end on rollers to allow for expansion, and the usual allowable load for expansion rollers is $P = 600\,D$; P = load, pounds per lineal inch of roller, and D = diameter of the roller, inches.

Table V. Areas of Contact and Pressures with Two Surfaces in Contact

Poisson's ratio = 0.3; P = load, pounds; P_1 = load per inch of length, pounds; E = modulus of elasticity.

Character of Surfaces	Maximum Pressure, s, at Center of Contact, lb per sq in.	Radius, r, or Width, b, of Contact Area, in.

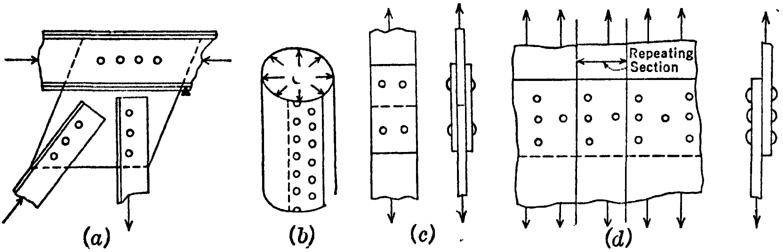
26. RIVETED AND WELDED JOINTS

Riveted Joints exist where two or more parts of a structure or machine are connected by rivets. Two types of riveted joints are usually recognized, those in structures or machines, Fig. 1*a*, and those in internal pressure vessels, Fig. 1*b*. They are further classified as *butt* joints, Fig. 1*c*, and *lap* joints, Fig. 1*d*. The short plates connecting the main plates in Fig. 1*c* are known as *butt* or *cover* plates and sometimes as *butt straps.* Depending upon the number of rows of rivets, joints are known as single, double, and triple riveted. Fig. 1*d* is a triple-riveted joint.



(*a*) (*b*) (*c*) (*d*)

FIG. 1

Stresses in Riveted Joints are of three kinds: (1) tensile stresses in the plates or members connected, (2) shearing stresses in the rivets connecting the plates, and (3) bearing stresses in the rivets and in the plates at the surface of contact with the rivets. In computing stresses it is assumed that the rivets are far enough from the end of the plate that the rivets will not tear through the plate and that all stresses are uniformly distributed over the area under consideration. Then the unit stresses, pounds per square inch, will be equal to the load, P, pounds, divided by the area, A, in square inches, or $s = P/A$.

First select a typical portion of the joint and then determine the load on the part selected and the area of each element which is under stress. For structural joints the entire joint is used, while for internal pressure vessels a strip called a *repeating* section is used. Fig. 2 shows such a repeating section, enlarged from Fig. 1*d*. The plate A will tend to tear apart at the section m–n and the plate B at section p–q, since the entire load must be carried across these reduced sections. The area of each plate is the same and the load is the same and therefore the tensile unit stress in each plate is $s_t = P/A_t$, in which $A_t = (b - d)t$, or $s_{t_{m-n}} = P/(b - d)t$. All the rivets being of the same size, each carries one-quarter of the load and therefore the total load carried across the section o–o will be $3P/4$ while the area $A_{t_{o-o}} = (b - 2d)t$, or $s_{t_{o-o}} = 3P/4(b - 2d)t$. The shearing unit stress in the rivets is $s_s = P/A_s$, where A_s is the area of the four rivets or $4\ \pi d^2/4$, or $s_s = P/\pi d^2$. The bearing unit stress in the plate, or rivet, is $s_b = P/A_b$, where A_b = the bearing area for four rivets, each of which is dt or a total of $4\,dt$, or $s_b = P/4\,dt$.

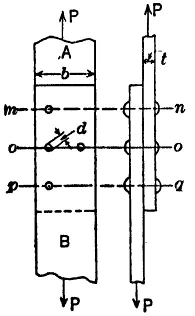


FIG. 2

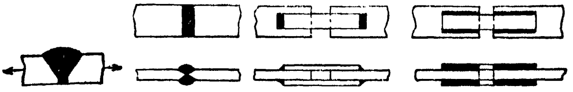
Allowable working stresses vary considerably, those given below representing two specifications widely used. The values are in pounds per square inch.

Table VII. Allowable Working Stresses

Kind of Stress	Am. Soc. Mech. Eng., Boiler Code	Am. Inst. Steel Cons., Structural, 1934
Tensile stress, net section	11,000	18,000
Shearing stress, power-driven rivets	8,800	13,500
" " hand-driven rivets	....	10,000
Bearing stress, power-driven rivets	19,000	24,000 *
" " hand-driven rivets	....	16,000 *

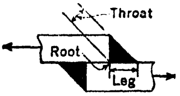
* Where rivets are in double shear these stresses may be increased 25 per cent.

Welded Joints have come into extensive use since the World War and are now (1936) used in many places in buildings, bridges, tanks, and machinery to replace or supplement riveted joints. Welding is defined as "a localized consolidation of metals by means of heat," and there are a number of methods of welding and a considerable variety of types of joints, of which a few are shown in Fig. 3. Stresses in welded joints are computed for shear and tension or compression. In *vee* joints the stress is computed for tension, or compression, by $s_t = P/A_t$, where A_t is the area of the weld, considered equal to the area of the thinnest plate connected. Stress in *fillet* joints is computed for shear, $s_s = P/A_s$, where A_s is equal to the length of all the welds times the thickness at the throat, the throat being measured as indicated in Fig. 4.



Single Vee Double Vee End Fillet Side Fillet

Fig. 3



Fillet

Fig. 4

The American Welding Society's Code for Fusion Welding and Gas Cutting in Building Construction, Edition 1930, recommends the following working unit stresses, all in pounds per square inch of throat weld: Shear, 11,300; tension, 13,000; compression, 15,000. Specifications on workmanship and on the qualifications of welders are rigid. Detailed information on workmanship, specifications and tests are given in the Report of Structural Steel Welding Committee of the American Bureau of Welding, 1931, and in Practical Design of Welded Steel Structures, *J. Am. Welding Soc.*, Aug., 1933, and also in the A.S.M.E. Boiler Code.

REINFORCED CONCRETE

By Theodore Crane

General Uses

Reinforced Concrete is concrete in which metal is embedded in such a manner that the two materials act together in resisting forces; the principal function of the concrete is to resist compressive stresses, and that of the reinforcement to resist tensile stresses.

The value of combining iron and concrete, to resist respectively tensile and compressive stresses in structural members, was first discovered in France about 1865. Since that time it has become one of the most widely used structural materials for bridges, roads, retaining walls, dams, tanks, and many other types of engineering structures, as well as for buildings. It is almost universally used for multi-story industrial buildings and garages.

The choice between a structural steel or a reinforced concrete skeleton depends on comparative cost, unless the architectural design requires the use of one of these materials. H-section steel cores, extending through four or five lower stories, can be successfully used when column sizes become excessive. For industrial loads, girderless floor systems are the most satisfactory. They provide better manufacturing facilities and a higher fire-resistance than so-called "mill-construction," or beam-and-slab design. For lighter types of occupancy as commercial and residential work, ribbed floor systems are more suitable.

27. SPECIFICATIONS

Concrete. See Non-metallic Materials, Section 12.

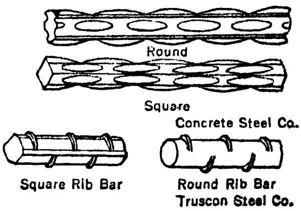


Fig. 1. Typical Types of Deformed Bars

Reinforcement. Expanded metal, triangular mesh, or wire fabric is often employed in slabs of moderate span, and in walls and partitions. The great bulk of reinforcement used, however, is in the form of bars, either plain or deformed, the deformations aiding the bond between the steel and concrete (see Fig. 1). Table I gives the areas, weights, and perimeters of standard round and square steel reinforcement.

The so-called "intermediate grade" of billet steel (see A.S.T.M. Specifications) can be generally used for all purposes where reinforcement is required. Rail steel, rerolled to rods and bars (see A.S.T.M. Specifications for Rail-steel Concrete Reinforcement Bars), is a satisfactory reinforcement in designs which do not require bending of the

Table I. Areas, Weights, and Perimeters of Round Rods and Square Bars

Size, in.	Round Rods							Square Bars			
	1/4	3/8	1/2	5/8	3/4	7/8	1	1/2	1	1 1/8	1 1/4
Area, sq in.	0.049	0.11	0.19	0.30	0.44	0.60	0.78	0.25	1.00	1.26	1.56
Weight per ft, lb	0.167	0.376	0.668	1.04	1.50	2.04	2.67	0.85	3.40	4.30	5.31
Perimeter, in.	0.78	1.18	1.57	1.96	2.35	2.75	3.14	2.00	4.00	4.50	5.00

rods. Wire reinforcement shall conform to the A.S.T.M. Standard Specifications for Cold-drawn Steel Wire for Concrete Reinforcement. Table II summarizes the chemical and physical properties of concrete reinforcement bars.

Steel reinforcement should be stored on racks, but need not be protected from the weather unless kept for long periods. A light coating of red rust does not injure the bond between steel and concrete, but heavy scale should be removed by wire brushing.

28. GENERAL PRINCIPLES OF DESIGN

Design. The design of concrete slabs, beams, and girders involves computation of the sectional area of steel required for strength in tension, and of concrete required for strength in compression. Diagonal tension, a function of the shear, is resisted by the concrete alone or with the aid of web reinforcement. Columns or struts supporting concentric loads are designed with a reinforced-concrete section in which each material is assumed to carry a portion of the compression. With comparatively heavy loads, spirals are used to increase the ultimate strength, or structural steel cores may be used to reduce the diameter of the column.

Placing of Reinforcement. All metal reinforcement should be accurately placed, supported at the proper height by concrete or metal chairs, and so secured as to prevent displacement during pouring of concrete. Reinforcement should be cold bent, as indicated on the drawings or steel lists, around a pin whose diameter is four or more times the least dimension of the rod or bar. It should be free from coatings that might destroy or reduce the bond, as heavy rust, scale, paint, grease, etc. Heating of reinforcement for bending should not be permitted. Sufficient lap should be provided at splices to transfer the stress between bars by bond and shear. Column rods should be lapped at least 24 diameters for deformed steel or 30 diameters for plain steel. Splices should not be made at points of maximum stress.

Insulation of Reinforcement. To protect the steel from corrosion and fire, minimum thickness of concrete should be provided around the reinforcement as follows: floor slabs and walls, 1 in. (some building ordinances require 1 1/2 in. for walls); beams, girders and columns, 1 1/2 in. (most building ordinances require 2 in. for girders and columns); footings or other principal structural members where concrete is deposited directly against the ground, 3 in. (most building ordinances require 4 in.); it is also desirable to provide 2 in. protection for all members exposed to the weather, as spandrel beams and exterior columns.

Contraction Joints. Volumetric changes normally occur when concrete hardens. When concrete is cured in dry air, shrinkage commences immediately after placement, due principally to loss of water by evaporation or absorption. The preliminary shrinkage, occurring while the concrete is plastic, is fairly rapid, particularly in thin members exposed to hot sun and wind. The secondary shrinkage, occurring after the member has assumed definite form, is much slower, and is influenced by atmospheric conditions and the character of mixture. Rich concrete shrinks more than lean; decreasing the water-cement ratio decreases the shrinkage.

Atmospheric temperature changes cause changes in volume during the life of a structure. The theoretical coefficient of expansion for concrete through normal temperatures is approximately 0.000,005. Changes in atmospheric moisture cause volumetric changes which may be as great as those due to temperature changes. To meet these conditions, joints must be provided at sufficiently frequent intervals to avoid exceeding the strength of the concrete, or sufficient reinforcement must be used so to distribute deformations caused by initial shrinkage and by temperature and moisture variations that they will not seriously affect the structure.

For buildings not over 300 ft long, the reinforcement required for the principal stresses usually is sufficient to distribute secondary stresses due to shrinkage or expansion. Longer structures should be separated by transverse joints so that free movement of the adjacent parts is possible. In beam-and-slab construction this can be done by erecting two

Elongation (8 in.), min, per cent	5	$\frac{1,200,000\dagger}{\text{Ten. str.}}$	$\frac{1,000,000\dagger}{\text{Ten. str.}}$
Cold bend without fracture:			
Bars < 3/4 in. diameter or thick bend, deg	180	180	180
* d/t =	2	3	4
Bars > 3/4 in. diameter or thick bend, deg	180	90	90
* d/t =	3	3	4

* d = diameter of pin about which specimen is bent; t = thickness or diameter of specimen.

† For bars over 3/4 in. in thickness or diameter, a deduction of 0.25 per cent from the percentages of elongation specified shall be made for each 1/32 in. of the thickness or diameter above 3/4 in.

For bars under 7/16 in. in thickness or diameter, a deduction of 0.5 per cent from the percentages of elongation specified shall be made for each decrease of 1/32 in. of the thickness or diameter below 7/16 in.

sets of columns supporting parallel floor beams on either side of the joint: a common footing may be used. In girderless construction, contraction joints are placed along the centers of bays, the two sections of which are designed as cantilevers. The break between sections should be complete, and exposed joints should be filled with an elastic joint filler.

Although most damages caused by temperature and moisture changes are traceable to contraction, expansion joints occasionally are necessary where sections of concrete are poured within rigid confines, particularly around the edges of concrete roof fills adjacent to parapet and penthouse walls. Comparatively thin members, particularly in exposed positions, should be lightly reinforced with $^3/_8$-in. round rods or wire fabric, to distribute deformations due to volumetric change and to prevent cracking. The amount of such reinforcement, of structural grade steel, may be taken as 0.3 per cent of the sectional area of the concrete.

Building Ordinances. Table III gives the allowable unit stresses applying to the design of reinforced concrete as now required by representative city ordinances and the Joint Standard Building Code. Unfortunately, there is wide variation in the requirements of different localities, and the engineer should obtain a copy of ordinances controlling his work. Outside of any local jurisdiction, the Joint Standard Building Code, published by the American Concrete Institute, is recommended as an excellent standard. Present practice (1935) is to design reinforced-concrete members on the basis of the allowable stresses in the materials, rather than on the ultimate stresses. Although most municipalities still assume fixed values for concrete mixed in certain specified proportions, it is preferable, when preliminary tests can be made, to compute allowable stresses as percentages of the ultimate compressive strength actually developed at the age of 28 days. The engineering societies have recommended this practice, which is illustrated by data taken from the Joint Code, and also by the requirements of the city of Philadelphia which permit this method to be used when proper control is exercised.

Table III. Allowable Unit Stresses in Reinforced Concrete under Static Loads

(From various codes)

Classification of Stresses	Allowable Stresses, lb per sq in.			
	1928, San Francisco*	1930, Boston†	1928, Chicago†	Joint Standard Building Code‡
Extreme fiber stress in concrete in compression in general	715	715	700	800
Adjacent to supports of continuous beams	825	825	700	900
Concentric compression in concrete	495	495	400	500
Shearing stress in concrete when no steel is provided to resist diagonal tension	....	44	40	40§
Vertical shearing stress when diagonal tension requirements are satisfied	132	132	135	120§
Bond stress:				
Between concrete and plain bars	88	88	70	80
Between concrete and deformed bars	110	110	100	100
Maximum tensile stress in steel reinforcement	18,000	18,000	18,000	18,000
Maximum tensile stress in cold-drawn steel wire	20,000	22,500	18,000	20,000

* Values based on a 28-day compressive strength of 2200 lb per sq in., corresponding to a mixture of 1 part cement to 6 parts combined aggregate, where the coarse aggregate is of granite or traprock. The proportions are by volume of cement to the combined aggregates, measured separately. For example, a 1 : 2 : 4 mixture might also be referred to as a 1 : 6 mixture.

† Values based on a 28-day compressive strength of 2200 lb per sq in.

‡ Values based on a 28-day compressive strength of 2000 lb. per sq in.

§ Values of 60 and 180 respectively may be used when special anchorage of longitudinal steel is provided.

29. BEAMS AND SLABS

Fundamental Assumptions. A plane cross-section of a beam, before bending, remains a plane section after bending; the modulus of elasticity of the concrete in compression remains constant within the assumed working stresses; the distribution of compressive stress in a beam is rectilinear; perfect adhesion exists between concrete and steel; in calculating the moment of resistance of reinforced-concrete beams and slabs, the tensile resistance of the concrete is negligible; the initial stress in the steel caused by contraction or expansion of the concrete is negligible, except in column design; the ratio of the modulus of elasticity of steel to concrete is expressed by the formula (notation given below):

$$n = \frac{E_s}{1000 f_c'} = \frac{30{,}000}{f_c'} \qquad (1)$$

Flexure Formulas for Rectangular Beams and Solid Concrete Slabs. (See Fig. 2.) The following notation is used: d = effective depth of beam, distance from extreme fibers in compression to center of gravity of tensile reinforcement, inches; b = width of beam or section of slab, inches; k = ratio of distance of neutral axis of cross-section from extreme fibers in compression to effective depth of beam; kd = distance of neutral axis from extreme fibers in compression, inches; j = ratio of distance between the center of compression of concrete and center of tension of steel to effective depth of beam, or ratio of arm of resisting couple to d; jd = distance between center of compression in concrete and center of tension in steel, or arm of resisting couple, inches; f_c = compressive unit stress in extreme fibers of concrete, pounds per square inch; f_c' = ultimate crushing unit strength of concrete at age 28 days, pounds per square inch; f_s = tensile unit stress in steel, pounds per square inch; A_s = area of cross-section of main tensile reinforcement, square inches; E_s = modulus of elasticity of steel, pounds per square inch; E_c = modulus of elasticity of concrete, pounds per square inch; n = modulus of elasticity of steel divided by modulus of elasticity of concrete, *i.e.*, $n = E_s/E_c$; M = bending moment, inch-pound; p = percentage of reinforcement, or $\frac{A_s}{bd}$; $K = \frac{1}{2} f_c jk$.

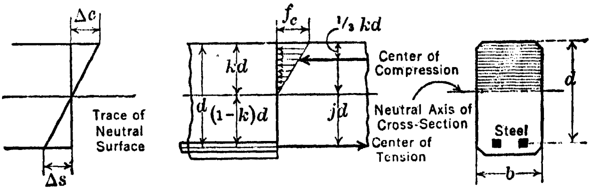

FIG. 2 Diagrams of Deformations and Stresses

Steel ratio, for balanced reinforcement,

$$p = \frac{1}{2\frac{f_s}{f_c}\left(\frac{f_s}{nf_c} + 1\right)} \qquad (2)$$

Ratio of distance of neutral axis of cross-section from extreme fibers in compression to effective depth of beam,

$$k = \sqrt{2pn + (pn)^2} - pn \qquad (3)$$

Ratio of arm of resisting couple to concrete depth,

$$j = 1 - \frac{k}{3} \qquad (4)$$

Concrete depth as controlled by bending moment,

$$d = \sqrt{\frac{M}{{}^1\!/_2 f_c jkb}} = \sqrt{\frac{M}{Kb}} \qquad (5)$$

Steel area as controlled by bending moment,

$$A_s = pbd \qquad (6a)$$

$$A_s = \frac{M}{f_s jd} \qquad (6b)$$

Formula 5 determines the depth of a slab or beam to resist a given bending moment without exceeding a specified unit stress in the concrete. If formula 5 is used, 6*a* or 6*b* may be used to determine the steel area. Formula 6*a* is for general use; formula 6*b* determines the sectional area of the reinforcement as a percentage of the concrete section, *bd*. In Table IV are given values of k, j, p, and K, for $n = 15$, as computed by the above formulas. If the value of p is computed from formula 2 or taken from Table IV, the result will be to supply the exact amount of steel necessary to " balance " the concrete. This procedure is satisfactory for slabs and rectangular beams, or for other members for which the concrete section has been determined by moment considerations. It

is inappropriate for the design of T-beams or others where the entire concrete section is not required by moment.

Fiber stresses,

$$f_s = \frac{M}{A_s jd} = \frac{M}{pjbd^2} \tag{7}$$

$$f_c = \frac{2M}{jkbd^2} = \frac{2pf_s}{k} \tag{8}$$

Formulas 7 and 8 are for checking fiber stresses of beams already designed.

Table IV. Formula Factors for Beams and Slabs

800	0.429	0.857	0.0107	146.9	900	0.429	0.857	0.0107	165.3

NOTE: Value of $n = 15$ throughout this table.

Flexure Formulas for T-Beams. (See Fig. 3.) The design of T-beams and T-girders is divided into two classifications: (1) That in which the neutral surface falls either within the flange or at the bottom of it. (2) That in which the neutral surface falls within the web.

In case 1, the design is the same as for rectangular beams, and formulas 2 to 8 apply. The width of flange, however, is used for the value of b, and the steel ratio p is based upon the total area bd.

In case 2, which is more frequent, neglecting the compression resisted by the web, let t = total slab thickness on either side of the web, inches; z = distance from the compression surface of the beam to the center of compression, inches; b' = width of web, inches; b = allowable width of flange, inches; $p = A_s/b'd$, that is, the steel ratio is based upon the area $b'd$. The remaining notation is the same as for rectangular beams.

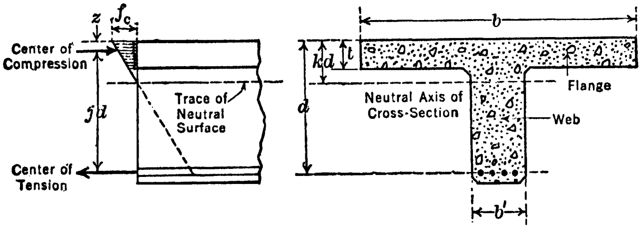

FIG. 3. Stress Diagram and Cross-section of a Reinforced-Concrete T Beam

Position of neutral axis,

$$kd = \frac{2ndA_s + bt^2}{2nA_s + 2bt} \tag{9}$$

Position of resultant compression,

$$z = \frac{3kd - 2t}{2kd - t} \cdot \frac{t}{3} \tag{10}$$

Arm of resisting couple, $jd = d - z$ (11)

Steel area as controlled by bending moment,

$$A_s = \frac{M}{f_s jd} \tag{12}$$

Fiber stresses,

$$f_s = \frac{M}{A_s jd} \tag{13}$$

$$f_c = \frac{Mkd}{btjd(kd - t/2)} = \frac{f_s}{n} \cdot \frac{k}{1 - k} \tag{14}$$

Formulas giving approximate results but erring slightly on the safe side are deduced by substituting

$$\left(d - \frac{t}{2}\right) \text{ for } jd, \quad \text{and} \quad (^1/_2) \text{ for } \left(1 - \frac{t}{2kd}\right)$$

This substitution gives:

Extreme fiber stress in concrete,

$$f_c = \frac{2M}{bt\left(d - \frac{t}{2}\right)} \tag{15}$$

Steel area,

$$A_s = \frac{M}{f_s\left(d - \frac{t}{2}\right)} \tag{16}$$

Shearing Stress. Rectangular beams and slabs should be checked for shear, as a measure of the diagonal tension, and the concrete area increased if the shear is excessive. The depth of T-beams, when economically designed, is generally controlled by shearing stress. Let V = total vertical shear at the section considered, pounds; v = total unit shearing stress at the section, pounds per square inch; $j = 0.875$ (an approximation used for shear computations); b = width of beam for rectangular beams (for T-beams replace b by b' the width of web), inches; d = effective depth of beam, inches. Then,

$$v = \frac{V}{bjd} \tag{17}$$

or

$$d = \frac{V}{bvj} \tag{18}$$

Equation 17 is used to check the unit shearing stresses on rectangular beams and slabs; the size of which is normally determined by bending-moment considerations. Equation 18 is used in the direct design of T-beams, etc., the maximum allowable value being substituted for v. It should be noted that the depths of T-beams are usually determined by shear, owing to the fact that the amount of concrete provided by the floor construction is normally more than sufficient to resist the compressive stresses due to moment.

Web Reinforcement. (See Fig. 4.) Stirrups or bent rods are used for web reinforcement in beams and girders of rectangular and T-section, as it is more economical to use such reinforcement, and correspondingly higher stresses, than to increase the size of the member.

The design of web reinforcement is as follows: Let v' = allowable unit shearing stress resisted by the concrete alone, pounds per square inch; A_s = cross-sectional area of stirrups, or of inclined portion of double-bent rods, square inches (in a U-shaped or W-shaped stirrup, this is the total cross-sectional area of all legs); f_s = allowable unit tensile stress in stirrups, pounds per square inch; s = spacing of stirrups, inches; remaining notation the same as above.

Then if $v'bjd$ represents the total shearing stress carried by the concrete,

$$s = \frac{f_s jd A_s}{V - v'bjd} \tag{19}$$

If it is required that the reinforcement is to be designed to take two-thirds of the total shearing stress, as specified in some codes, the formula becomes

$$s = \frac{3}{2}\frac{f_s jd A_s}{V} \tag{20}$$

These formulas apply to vertical stirrups. Inclined stirrups or inclined bars, forming a part of the main tensile reinforcement may be designed or checked by the same formulas, by multiplying the value of the shear by the sine of the angle of inclination to the horizontal.

If L = clear span, feet, the distance from the support through which either stirrups or bent bars are required for uniformly loaded beams is given by

$$x = \frac{L}{2}\left(1 - \frac{v'}{v}\right) \tag{21}$$

Stirrups usually are placed vertically, and are either $^3/_8$-in. or $^1/_2$-in. round rods, bent to a U- or W-shape. The maximum spacing for stirrups should be limited to $^3/_4$ × depth of beam; this also is the maximum distance through which the inclined portion of a longitudinal rod, or several rods, bent at the same section, should be considered effective as web reinforcement (see Fig. 4). The diameter of the rod used for stirrups should not exceed $^1/_{50} \times$ depth of beam. Stirrups should encircle the main longitudinal reinforcement, all free ends being anchored by hooks.

Bond. As the tensile stress in the reinforcement is transmitted from the concrete, the rods or bars must have sufficient surface area to avoid exceeding the unit bond stress per square inch. If u = unit bond stress, pounds per square inch, and Σo = sum of perimeters, inches, of all horizontal rods under tensile stress at the section considered,

$$u = \frac{V}{(\Sigma o)jd} \quad \text{or} \quad \Sigma o = \frac{V}{ujd} \tag{22}$$

It is customary to check the bond stress after the design is completed; if the value is excessive, smaller rods should be used and the number increased, since this increases the surface area of the steel. Limiting values for bond stress are usually 80 lb per sq in. for plain rods or bars, and 100 lb per sq in. for deformed types.

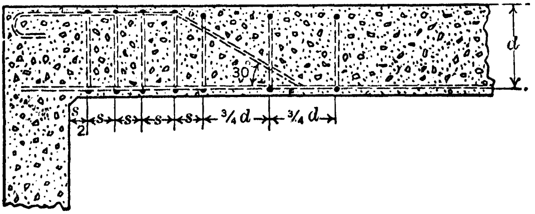

FIG. 4. Diagram of a Web-Reinforcement in a Rectangular or T Beam

Anchorage of Reinforcement. Besides the matter of bond, it is necessary to anchor the main longitudinal reinforcement at terminations where slabs, beams, or girders rest upon walls or frames, by means of hooks, into other reinforced-concrete members (see Fig. 5). Where continuous over supports, it is customary to carry half the longitudinal reinforcement of each beam to the $^1/_4$ or $^1/_5$ point of the adjacent span. This practice provides adequate anchorage; the remaining steel is usually stopped at the center line of the support.

An embedment of 50 diameters of a rod, or side of a square bar, is required to develop an allowable unit stress of 16,000 lb per sq in. in the steel, and an embedment of 56 diameters to develop a unit stress of 18,000 lb per sq in. (u = 80 lb per sq in.). Embedments of 40 diameters and 45 diameters correspond, respectively, to a strength of 16,000 and 18,000 lb per sq in. for deformed steel (u = 100 lb per sq in.).

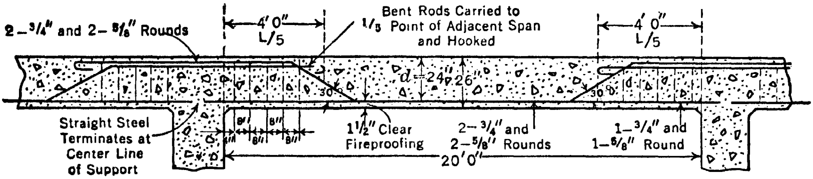

FIG. 5

Bending Moments and External Shears. Bending moments and vertical shears for continuous and restrained beams as well as for those of single spans simply supported are given on pp. 5-26 to 5-28 and p. 5-20. These values also apply to reinforced-concrete members subjected to flexure, but for continuous spans they are modified to conform to the conditions of partial restraint existing in concrete frames. Also to provide for possible variable live loads, the values of the positive bending moments used in concrete design usually are taken larger than the theoretical values.

As the function of the reinforcement is to resist the tensile stresses, the typical arrangement for beams other than cantilever is to place the rods near the bottom face throughout the central portion of the span. For beams simply supported, about two-thirds of the main tensile reinforcement consists of straight rods or bars, the other one-third being bent up at the $^1/_5$ point of the clear span and anchored into the supports to resist any negative moment resulting from the monolithic construction.

For continuous or restrained beams, it is usual to raise one-half the main tensile reinforcement at the points of inflection, assumed to be the $^1/_5$ points of the clear span, and, in the former case, to carry the reinforcement to the $^1/_4$ point of the adjoining span. This provides approximately equal areas near the bottom of the beam at mid-span and near the top of the beam over supports, which corresponds to the general design practice of using approximately equal coefficients for both positive and negative moments in the design of continuous members. Raising a portion of the main longitudinal reinforcement also helps to resist diagonal tension and usually permits the omission of one or two stirrups at each end of the beam.

The following equations for determining maximum bending moment are recommended by the Joint Standard Building Code for freely supported or slightly restrained continuous beams, or slabs of approximately equal spans, under uniform load.

(1) Beams and slabs of one span: positive moment near center,

$$M = \frac{Wl}{8} \tag{23}$$

(2) Beams and slabs continuous for two spans only: positive moment near center of each span,

$$M = \frac{Wl}{10} \tag{24}$$

negative moment over interior support,

$$M = \frac{Wl}{8} \tag{25}$$

(3) Beams and slabs continuous for more than two spans: positive moment near center and negative moment at support of interior spans,

$$M = \frac{Wl}{12} \tag{26}$$

positive moment near centers of end spans and negative moment at first interior support,

$$M = \frac{Wl}{10} \tag{27}$$

(4) Negative moment at end supports for Cases 1, 2, and 3,

$$M = \text{not less than } \frac{Wl}{24} \tag{28}$$

In these equations M = bending moment, pound-inches; W = total load on the beam or slab, pounds, including its own weight; l = length, inches, taken as the center-to-center span for beams simply supported, and as the clear span for continuous or restrained beams. The equations apply only to beams or slabs under uniform load and, in continuous members, to those of approximately equal spans. If the spans are substantially unequal, or subjected to other than uniformly distributed loads, the actual bending moments and shears should be computed by the methods given in the section on Beams, pp. 5-19 to 5-36. The computation of moments for continuous girders and other members subjected to concentrated loads may be simplified by determining the moments as if the members were simply supported, and then multiplying by a reducing factor corresponding to the condition of end restraint, *i.e.*, $^4/_5$ for semi-continuity and $^2/_3$ for full continuity. The design of continuous members should always provide steel over support at least equal to the amount required in mid-span to resist the negative moment.

The external vertical shear is computed as a measure of the diagonal tension, which, in reinforced-concrete members subject to flexure, is a combination of horizontal and vertical shear. For both simply supported and continuous members, shears are computed as described in the section on Beams, pp. 5-19 to 5-36. For members symmetrically loaded, the maximum shear, occurring at the face of the support, equals $^1/_2$ load, except as influenced by the conditions of end restraint.

Rectangular Beams.

Example. Required to design a rectangular beam, 20-ft clear span, fully continuous at supports, for a uniformly distributed load of 1500 lb per ft, including weight of beam.

Specification data: f_c = 650; f_s = 18,000; n = 15; v' limited to 40; maximum allowable vertical shearing stress (v) with web reinforcement = 120.

By formula 26, $M = Wl/12 = (30{,}000 \times 20 \times 12)/12 = 600{,}000$ lb-in.

By formula 5, $d = \sqrt{M/Kb} = \sqrt{600{,}000/(100.8 \times 10)} = 24.39$ in., = 24 in. (approximately), where breadth b is assumed as 10 in.; k from Table IV.

By formula 6, $A_s = pbd = 0.0063 \times 10 \times 24 = 1.51$ sq in.

Accept a total depth of 26 in. and a width of 10 in., with two $^5/_8$-in. rounds and two $^3/_4$-in. rounds

The value of b should be chosen as small as practicable, unless headroom is limited, deep, narrow beams being more economical. Sufficient width should be provided to give a clear space of at least 1 in. between rods and the required fireproofing on the sides. The overall depth of a beam or girder should not be more than $3b$.

Testing the shear by formula 17, $v = V/bjd = (1500 \times 10)/(10 \times 0.875 \times 24) = 71.5$ lb per sq in. As this is more than v', the value allowed for plain concrete, and less than the limit for v, 120 lb, the design is acceptable, provided web reinforcement is used. The web reinforcement is computed as follows:

By formula 20, $s = (3/2)(f_s jdA_s/V) = (3/2)\ \{(18{,}000 \times 0.875 \times 24 \times 0.22)/15{,}000\} = 8.3$ in., where A_s = cross-sectional area of the two legs of a U-shaped stirrup, made of $^3/_8$-in. round rod.

By formula 21, $x = (L/2)\{1 - (v'/v)\} = (20/2)\{1 - (40/72)\} = 4$ ft 6 in.

The first stirrup is placed 4 in. ($^1/_2 s$) from the face of the support. Four more stirrups, 8 in. apart, provide web reinforcement out to the section where the bent rods are effective. Beyond this section, as shown by equation 21, none is needed.

Testing the bond stress at face of support by formula 22, $u = V/[\Sigma ojd] = 15{,}000/[\{(2 \times 1.96) + (2 \times 2.36)\} \times 0.875 \times 24] = 82.6$ lb per sq in. This value is satisfactory for plain rods. The arrangement of reinforcement is shown in Fig. 5.

Table V gives the safe loads on rectangular beams of various dimensions and reinforcements, designed according to the above principles.

Loads to left of upper zigzag line develop shears greater than 40 lb per sq in. Loads to left of lower zigzag line develop shears greater than 60 lb per sq in. Loads in italic figures produce bond stresses greater than 100 lb per sq in. For semi-continuous spans ($M = WL/10$), multiply tabular load by 1.25. For fully continuous spans ($M = WL/12$), multiply tabular load by 1.50. When using this table for continuous or semi-continuous spans, the shear and bond stresses should be investigated.

Slabs. The design of solid concrete slabs is substantially the same as that of rectangular beams. If the panels are square or nearly so, it is necessary to determine the load to be distributed in each direction. If the longer dimension is greater than 1 $^1/_2$ × shorter dimension, as it usually is, the slab is designed to carry all the load on the shorter span, and so-called " shrinkage " steel, comprising $^3/_8$-in. rounds spaced 1 ft 6 in. centers, is considered adequate in the longer direction.

The total load on a strip of slab 1 ft wide, spanning between supports, is obtained by multiplying the unit load per square foot by the span. This strip is then treated as a rectangular beam of breadth b = 12 in.

Example. Required: to design a slab, 7-ft span, fully continuous at supports, to carry a superimposed load of 125 lb per sq ft. Specification data: Same as in the example of a rectangular beam.

Assuming a slab thickness of 4 in., weighing 48 lb per sq ft, total load per square foot = 125 + 48 = 173 lb per sq ft.

On a strip of slab 1 ft wide, total load = $173 \times 7 = 1211$ lb.
By formula 26, $M = \underline{Wl/12} = \underline{(1211 \times 7 \times 12)/12} = 8477$ lb-in.
By formula 5, $d = \sqrt{M/Kb} = \sqrt{8477/(100.8 \times 12)} = 2.65$ in.
By formula 6, $A_s = pbd = 0.0063 \times 12 \times 2.65 = 0.20$ sq in.
Accept a total depth of 4 in. (approximately 1 in. below the reinforcement) with $^3/_8$-in. rounds, 7 in. on centers.

Rods should not be spaced at a distance greater than $2\,^1/_2 \times$ total depth of slab; the use of very small rods at close spacings is uneconomical.

Testing the shear by formula 17, $v = V/(bjd) = 605/(12 \times 0.875 \times 2.65) = 21.7$ lb per sq in. As this is less than the limiting value, v', the design is accepted.

Testing the bond stress at face of support, by formula 22, $u = V/(\Sigma ojd) = 605/\{(1.71 \times 1.18) \times 0.875 \times 2.65\} = 129$ lb per sq in., where 1.71 = number of rods per foot of width, and 1.18 = perimeter of each rod. The value is rather high but may be accepted for deformed rods, provided the reinforcement is anchored at terminations and lapped over supports. Fig. 6 shows the arrangement of reinforcement.

Table VI gives the safe loads on solid concrete slabs of various dimensions and reinforcements, designed according to the above principles.

For loads shown, unit shearing stresses are less than 40 lb per sq in. Loads to left of zigzag line produce bond stresses greater than 100 lb per sq in. For semi-continuous spans ($M = WL/10$), multiply tabular load by 1.25. For fully continuous spans ($M = WL/12$), multiply tabular load by 1.50. When using the table for continuous or semi-continuous spans, the shear and bond stresses should be investigated.

T-Beams. When designing a floor system comprising slabs, beams, and girders, the slabs are first considered. These are designed as in the previous example, and the load carried by a T-beam, for which the floor slab acts as a flange, is found by multiplying the unit load per square foot of floor by the area which the beam supports, and adding to the product any other incidental loads and the weight of the stem of the beam.

The loads carried by T-girders, usually a combination of concentrated loads due to beam reactions, and the uniformly distributed weight of the girder itself, are used to compute the bending moment, which is then employed in exactly the same way as with uniformly distributed loads.

For purposes of design in computing the sectional-area of concrete available to resist compressive stresses, the width of slab which may be considered as acting as the flange of a T-beam should not exceed $1/4$ of the span-length of the beam. See Fig. 7.

The overhanging width on either side of the web should not exceed 8 × slab thickness nor $1/2 \times$ clear distance to next beam. In angle beams, the overhanging width of flange should be limited to $1/12 \times$ span or $1/2 \times$ clear distance to next beam. It is always necessary to pour the floor slab forming the flange of the beam monolithically with the web, and there must be steel in the form of stirrups or bent rods to bond the flange to the web.

FIG. 6

The critical section for compression in T-beams and T-girders, continuous over supports, is at the face of the support. As the negative moment acts on the rectangular section of the web, the stress in the concrete at these sections is always higher than through mid-span. However, as only a short section of the beam is in compression at this point, good practice permits an increase of 15 per cent in the compressive stress. The straight bars in the bottom of the beam also act as compressive reinforcement, provided they are extended a sufficient distance beyond the face of the support to develop their stress in bond.

FIG. 7

Example. Required to design a T-beam, 20-ft clear span, with ends semi-continuous, to carry a uniformly distributed load of 2000 lb per ft including the weight of the beam. Slab thickness = 4 in.; specification data, same as in the example of a rectangular beam.

Determining the depth by shear by formula 18, $d = V/(b'vj) = 20{,}000/(10 \times 120 \times 0.875) = 19$ in., where the width of the beam is assumed as 10 in., and j is taken as 0.875.

The moment by formula 27 $= M = Wl/10 = (40{,}000 \times 20 \times 12)/10 = 960{,}000$ lb-in.

By formula 16, $A_s = M/[f_s\{d - (t/2)\}] = 960{,}000/[18{,}000\{19 - (4/2)\}j = 3.14$ sq in.

Accept a total depth of 21 in., with four 1-in. rounds. The width of 10 in. will allow 1 in. between each rod and a protection of $1\,1/2$ in. on each side. Raise two rods over support as shown in Fig. 8.

By formula 20, $s = (3/2)(f_s jdA_s/V) = (3/2)\{(18{,}000 \times 0.875 \times 19 \times 0.44)/20{,}000\} = 9.87$ in., where A_s = cross-sectional area of steel in the four legs of a W-shaped stirrup ($3/8$-in. round rod).

By formula 21, $x = (L/2)\{1 - (v'/v)\} = 10\{1 - (40/120)\} = 6$ ft 8 in., where v has its limiting value, as the beam was designed on that basis. The first stirrup is placed 4 in. ($1/2s$) from the face of the support. Four more stirrups, 8 in. apart, provide web reinforcement out to the section where the bent rods are effective. Fifteen inches beyond this section, as shown by Fig. 8, three stirrups are placed 12 in. apart.

Testing for bond stress at face of support by formula 22, $u = V/\Sigma ojd = 20{,}000/\{(4 \times 3.14) \times 0.875 \times 19\} = 96$ lb per sq in. This value is satisfactory for deformed rods.
The arrangement of reinforcement is shown in Fig. 8.

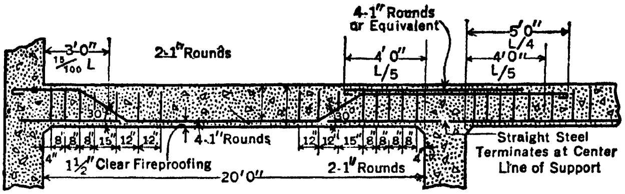

Fig. 8

Table VII gives the safe loads on T-beams of various dimensions and reinforcements designed according to the above principles.

Loads to the left of zigzag line produce shearing stresses greater than 120 lb per sq in. on the area $b'jd$. For stirrups see p. 5–65. Loads in italic figures produce bond stresses greater than 100 lb per sq in. For anchorage see p. 5–66. For semi-continuous spans ($M = WL/10$), multiply tabular load by 0.83. For simply supported spans ($M = WL/8$), multiply tabular load by 0.67. When using this table for semi-continuous and simple spans, the bond stresses should be investigated.

Ribbed Floor Construction. For floors of apartment houses, hotels, institutional buildings, and others for light occupancy (superimposed loads 30 to 100 lb per sq ft), the ribbed constructions are particularly suitable. These comprise a series of concrete ribs, 4 or 5 in. wide, separated by terra-cotta blocks, gypsum or concrete units, metal or wood pans. Rib spacing varies from 16 to 30 in., depending on the width of block or void. A continuous slab, from 2 to 3 in. thick, forms the structural surface of the floor. Plaster is applied directly to the soffits of the blocks used as fillers; under the pans, metal lath is used as a plaster base. All these designs may be used with structural-steel or reinforced-concrete frame. Bridging joists should be used on long or very heavily loaded spans.

As the structural units in such systems are actually small T-beams (the fillers, except in terra-cotta and concrete, acting merely as voids) the design is substantially the same as for T-beams. The following example applies to the metal-pan system (see Fig. 9); the same method is used for all ribbed designs.

Example. Required to design a pan system 20 ft between faces of supports. Live load 60 lb per sq ft; allow 22 lb per sq ft for floor fill, finish and plaster, end condition fully continuous. Specification data: f_c = 700 lb per sq in.; f_s = 18,000 lb per sq in.; v' limited to 40 lb per sq in.; $n = 15$; minimum thickness of concrete over metal = 2 $^1/_2$ in.

Choosing a pan 20 in. wide and 10 in. deep, with a 2 $^1/_2$ in. topping, from the manufacturer's catalog, the weight per square foot = 58 lb. Loads per square foot are: live load = 60; floor finish, etc. = 22; weight of construction = 58; total load = 140. Load per linear foot of rib = 140 × 25/12 = 291 lb, in which 25 in. is the center-to-center spacing of ribs. Total load on each rib = 291 × 20 = 5820 lb.

By formula 26, the moment $M = Wl/12 = (5820 \times 20 \times 12)/12 = 116{,}400$ lb-in.

By formula 16, $A_s = M/[f_s\{d - (t/2)\}] = 116{,}400/[18{,}000 \times 10] = 0.647$ sq in., where $d = (10 + 2\,^1/_2) - 1.25 = 11.25$ in.; $t/2 = 2.5/2 = 1.25$ in.

Accept two $^5/_8$-in. rounds in each rib (A_s = 0.62 sq in.).

The stress in the concrete is then checked. By formula 14 and Table IV,

$$f_c = \frac{Mkd}{bt\{kd - (t/2)\}jd} = \frac{116{,}400 \times 0.368 \times 11.25}{(25 \times 2.5)\{(0.368 \times 11.25) - 1.25\}(0.877 \times 11.25)} = 270 \text{ lb per sq in.}$$

Accept a 10-in. pan with 2 $^1/_2$-in. topping.

The maximum shear in the ribs at face of support is checked by formula 17, $v = V/b'jd = 2910/(5 \times 0.875 \times 11.25) = 59$ lb per sq in., where b' = average width of the concrete rib for metal tile, equal to 5 in. In this computation, also, the conventional value of 0.875 is used for j instead of the value 0.877 given by Table IV.

Since v is more than the limiting value, v', tapered pans (see Fig. 9) should be used adjacent to supports to provide additional concrete to resist the compressive stress, due to negative moment, as well as the shearing stress.

Testing for bond stress at face of support, by formula 22, $u = V/\Sigma ojd = 2910/\{(2 \times 2.35) \times 0.875 \times 11.25\} = 63$ lb per sq in., where j is taken as 0.875. Deformed rods are unnecessary.

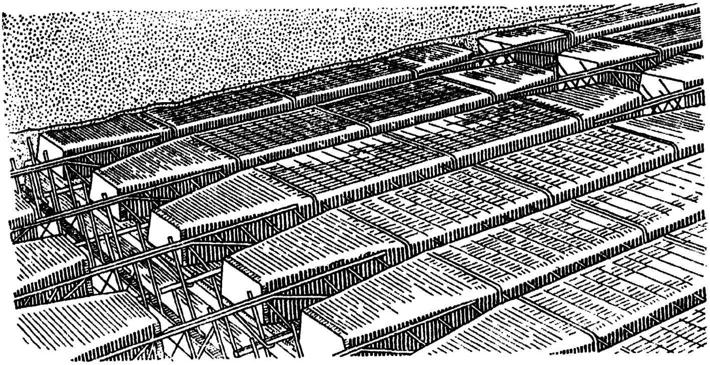

FIG. 9. Ribbed Floor Construction, Tapered Type Pan Used at Supports.

One $^5/_8$-in. rod is raised at the $^1/_5$ point of the clear span and carried over the support to the $^1/_4$ point of the adjoining span to provide a sectional area of steel over supports equal to that at mid-span.

30. COLUMNS

The principal types of reinforced-concrete columns are the tied or hooped, spiraled, and cored, the last being actually a steel column. The main columns of a building should never be less than 12-in. in diameter or in least width; good practice requires a minimum 16-in. diameter for round columns supporting girderless floor construction, and a minimum 14-in. thickness for exterior columns of industrial buildings. The diameter or least width should not be less than $^1/_{15}$ the average center-to-center span of the supported bay nor longer than 11 × least lateral dimension of the column, unless the normal load is reduced. Dowels are used between footings and superimposed columns. Splices in vertical reinforcement should be made by lapping the rods a length of at least 24 bar diameters.

Tied Columns (see Fig. 10) are economical for comparatively light loads, as those carried in the upper stories of buildings. The ratio p of the cross-section of area of the vertical reinforcement to effective concrete area, usually taken as the gross sectional area, should not be less than 0.5 per cent nor should more than 2 per cent be considered in the computations. At least 4 rods, $^5/_8$-in. diameter, should be placed between 2 and 3 in. from the face of the column, enclosed by $^1/_4$-in. diameter ties spaced not over 12 in. apart. As both maximum and minimum percentages of steel are controlled by building ordinances, it is usually desirable to increase the column size or to use a richer mixture rather than to add vertical steel to carry load. It is extremely important, however, to have sufficient vertical reinforcement to resist bending, particularly for unsymmetrical loads.

Spiraled Columns (see Fig. 10) are usual for the interiors of buildings designed for heavy loads. Although a minimum amount of vertical reinforcement is required to resist bending stresses, the greatest economy is obtained by using rich mixtures and as large a percentage of spiral as the code or specification will permit. The vertical reinforcement should comprise at least 6 bars of $^1/_2$-in. minimum diameter, with cross-sectional area not less than 1 per cent nor more than 6 per cent of the core. The spiral is expressed as a percentage of the volume of the enclosed concrete and varies from $^1/_2$ to 2 per cent (see equation 32 below). The ratio of the per cent of spiral reinforcement to the per cent of vertical reinforcement should not be less than $^1/_4$. The spiral reinforcement should consist of evenly spaced, continuous spirals held firmly in place by at least three vertical spacer bars. The spacing of the spirals should not be greater than $^1/_6$ the diameter of the core nor over 3 in.

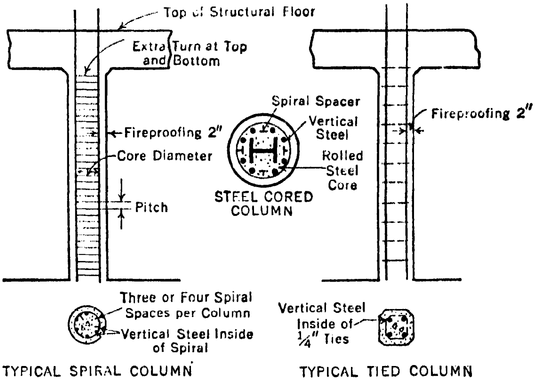

Fig. 10

Cored Columns (see Fig. 10) are built of steel wide-flange sections enclosed by a minimum of 4 in. of concrete, reinforced with at least 0.5 per cent of vertical reinforcement and 0.5 per cent of spiral. The structural-steel core is then designed on a basis of axial compression, using a stress of 15,000 to 18,000 lb per sq in., according to the code or specification. No allowance is made for the concrete casing. The ratio of the unsupported height to the least radius of gyration of the structural-steel section should not exceed 120.

The Effective Area of a Column is that area which is considered as capable of carrying load. With tied columns, some city ordinances and many designers permit the gross cross-sectional area to be used, as in the following example; but the effective area of spiraled columns is always considered as the section enclosed within the spiral, the outer casing, usually 2 in. thick, being disregarded.

Formulas for Columns. The following formulas apply to the design of tied and spiraled columns. Let A = effective cross-sectional area of column, square inches; p = ratio of area of vertical steel to effective sectional area of concrete; P = total safe axial load, pounds, on column whose length $\overset{=}{<}$ 11 × least cross-sectional dimension; n = ratio of modulus of elasticity of steel to modulus of elasticity of concrete; f'_c = ultimate crushing unit strength of concrete at age 28 days, pounds per square inch; f_c = average unit compressive stress, in concrete, pounds per square inch; f = average unit compressive stress, P/A, in the column, pounds per square inch; D = core diameter in spiral columns, inches; a = cross-sectional area of spiral reinforcement steel; s = spacing of spiral reinforcement, *i.e.*, pitch, inches.

For tied columns, the total safe load,

$$P = 0.225f'_cA\{1 + (n - 1)p\} \tag{29}$$

For spiraled columns, the total safe load,

$$P = f_cA\{1 + (n - 1)p\} \tag{30}$$

where $$f_c = 300 + (0.10 + 4p)f_c' \qquad (31)$$

$$\text{The percentage of spiral reinforcement} = \frac{4a}{Ds} \times 100 \qquad (32)$$

Example of Tied Column Design. Required: to design a round column to carry an axial load of 150,000 lb, including weight of column. For economy, use the minimum amount of vertical reinforcement, i.e., $p = 0.5$ per cent of the effective area, which is taken as the gross cross-section of the column. Specification data: $f'_c = 2000$ lb per sq in.; $n = 15$.

By formula 29, $P = 0.225 f'_c A\{1 + (n - 1)p\}$

Then $f = P/A = 0.225 f'_c\{1 + (n - 1)p\}$

Substituting the specification data for this example, $f = 450\{1 + (14 \times 0.005)\} = 482$ lb per sq in., and $A = P/f = 150{,}000/482 = 311$ sq in., which area is given by a 20-in. round column, whose area is 314 sq in.

Area of vertical steel $= A \times p = 314 \times 0.005 = 1.57$ sq in.

Accept six $^5/_8$-in. round rods, with $^1/_4$-in. round ties spaced 12 in. on centers. The steel rods are placed 2 in. inside the surface. Splices at floor levels are lapped 18 in. Note that the value of f can be used repeatedly for all columns designed under the same specification unless it is necessary to increase the economical percentage of vertical steel.

Table VIII gives the safe loads on square tied columns of various dimensions and reinforcements designed according to the above principles.

Example of Spiraled Column Design. Required to design a spiraled column to carry an axial load of 425,000 lb including weight of column. Assume a ratio of 4 per cent vertical and 1 per cent spiral, based on the core area. Specifications data: $f'_c = 2500$ lb per sq in.; $n = 12$.

By formulas 30 and 31, $P = A\{1 + (n - 1)p\}f_c$, and $f_c = 300 + (0.10 + 4p)f'_c = 300 + \{0.10 + (4 \times 0.04)\}2500 = 950$ lb.

Then $f = P/A = \{1 + (11 \times 0.04)\} \times 950 = 1368$ lb per sq in.

$A = P/f = 425{,}000/1368 = 310.6$ sq in.

This area is given by a 20-in. round column, whose area = 314 sq in. Allowing 2 in. for fireproofing, the gross diameter is 24 in.

Area of vertical steel $= A \times p = 314 \times 0.04 = 12.56$ sq in.

Accept eleven 1 $^1/_4$-in. round rods. Spiral steel, $^3/_8$-in. round, 2 $^1/_4$-in. pitch. (From equation 30, this corresponds to a spiral reinforcement of 0.98 per cent.) The vertical rods are placed inside the spiral. Use three spiral spacers (some codes require four). The vertical steel is lapped 2 ft at floor levels.

Table IX gives the safe loads on spiral columns of various dimensions and reinforcements, designed according to the above principles.

31. FOOTINGS

The Function of a Footing is to distribute concentrated loads from walls or columns over a sufficiently large area to bring the pressure within the safe bearing capacity of the soil or rock. Plain concrete footings may be used beneath walls or columns carrying small loads, but reinforced designs are more economical for heavy construction.

Types of Reinforced-concrete Column Footings (see Fig. 11) are: the isolated column footing; the combined or continuous footing, carrying two or more columns and constructed as an inverted beam; the cantilever footing, in which the eccentricity of an exterior footing is resisted by a strap connected with an adjacent interior footing. All types may be used either with or without piles, and the continuous footing may be developed as a mat to cover the entire foundation area. Footings for independent columns are designed in both stepped (Fig. 11*a*) and pyramidal (Fig. 12*c*) forms. The use of a pedestal between the footing slab and the base of the superimposed column is of value in reducing the unit compression on the top surface of the footing.

The load used in determining the soil bearing area of a footing is the load used in the design of the column in the story immediately above the footing, plus any live load or dead load in that story, plus the estimated weight of the footing itself. Footing areas should be proportioned for dead load alone or, in industrial buildings, for the dead load plus a fraction of the live load.

The design load, used to determine the thickness and reinforcement of a footing slab, is the load defined above, less the weight of the footing. Individual column footings must be centered beneath the column which they support. If more than one column rests on the same footing, the center of gravity of the foundation area must coincide with the center of gravity of the loads.

Reinforced-concrete footings are designed by the same formulas as concrete beams and slabs. The footing must be sufficiently strong to resist the stresses produced by bending moment and diagonal tension, and most building ordinances contain a requirement for "punching shear." A two-way reinforcement, of plain or deformed rods, is

used in the slab and dowels to connect the footing slab to the basement column. Pedestals may be used to obtain a uniform height from which to start the first tier of columns.

Isolated footings, preferably square in plan, are generally used unless the proximity of a property line or other obstruction makes a concentric design impossible. Under such conditions, the combined footing, or the continuous wall footing, are both preferable to the cantilever type which is highly indeterminate except when used over piles.

The design of an isolated column footing involves determining the area of the footing slab, the design load, the depth as controlled by punching shear, where this is specified by code, and the steel area as controlled by moment. The diagonal tension, compression in the concrete, and bond stress in the steel are then checked. The requirements of diagonal tension may demand increasing the thickness of the footing slab near its edge, but the concrete stresses are seldom critical if the other considerations are met, and high bond stresses may be avoided by using comparatively small rods and hooking the ends.

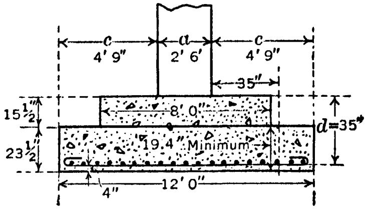

Fig. 12-*a*

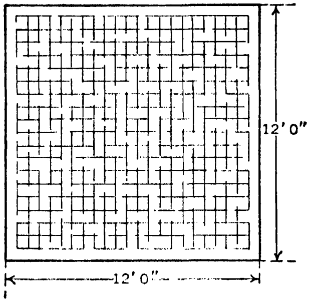

Fig. 12-*b*

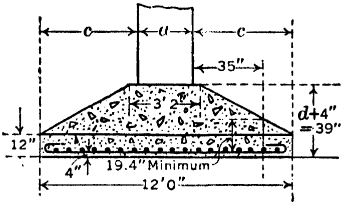

Fig. 12-*c*

Example. Required to design an isolated footing for a column of 30 in. square, sustaining a load of 525,000 lb, including the weight of the column. Soil pressure, 2 tons per sq ft. Specification data: f_c = 650 lb per sq in.; f_s = 16,000 lb per sq in.; v limited to 40 lb per sq in.; punching shear limited to 120 lb per sq in.; n = 15; u limited to 100 lb per sq in.

Estimating the weight of the footing at 50,000 lb, area of footing slab = 575,000/4000 = 144 sq ft.

Choosing a square footing, 12 × 12 ft, w = 525,000/144 = 3346 lb per sq ft. Depth as controlled by punching shear.

$$d = \frac{(\text{Area of footing} - \text{Area of column}) \times w}{(\text{Perimeter of column}) \times (\text{Allowable punching shear})} = \frac{(144 - 6.25) \times 3646}{4 \times 30 \times 120} = 34.9 \text{ in.}$$

Accept a total depth of 39 in.

If a = width of side of column or pedestal, and c = projection of footing slab, both in feet (see Fig. 12),

$$M = 6w(a + 1.2c)c^2 = 6 \times 3646\{2.5 + (1.20 \times 4.75)\} \times 22.53 = 4{,}047{,}000 \text{ lb-in.}$$

By formula 6b, $A_s = M/(f_s jd) = 4{,}047{,}000/(16{,}000 \times 0.875 \times 35) = 8.26$ sq in. Accept nineteen 3/4-in. rounds.

Thickness d' of footing slab, as controlled by diagonal tension at distance d from face of column or pedestal (d and d' are both in inches),

$$d' = \frac{(\text{Area outside distance } d)\ w}{jv\ (\text{Perimeter at distance } d)} = \frac{[144 - \{2.5 + (35/6)\}^2] \times 3646}{0.875 \times 40 \times \{2.5 + 35/6\} \times 4 \times 12} = 19.4 \text{ in.}$$

By formula 8, minimum width of footing at top, in feet $= b = \dfrac{2M}{jkf_c d^2 \times 12}$

$$M/(1.99 \times f_c \times d^2) = 4{,}047{,}000/(1.99 \times 650 \times 1225) = 2.55 \text{ ft.}$$

By formula 22, $u = V/[\Sigma o]jd = \dfrac{(144 - 6.25) \times (3646/4)}{(19 \times 2.35) \times 0.875 \times 35} = 93$ lb per sq in., which is acceptable for deformed rods. Fig. 12a shows the footing arranged in a stepped form; Fig. 12_c shows the same footing arranged in a pyramidal form.

It should be noted that this example follows the procedure of most building ordinances in considering "punching shear," which usually determines the depth. Table X follows the Joint Code and gives a somewhat different design which represents advanced practice and can be advantageously applied outside of any particular jurisdiction.

32. GIRDERLESS OR FLAT SLAB CONSTRUCTION

For building three or more bays wide, where column locations give approximately square bays of equal or nearly equal size, girderless or flat slab construction is the most satisfactory for heavy loads, as are required for industrial occupancy. The advantages are a saving in story height, due to the elimination of beams and girders, better lighting facilities, and structural economy. The flared column heads are characteristic of this system, which may be designed either with or without drops over the columns. If depressed panels, usually referred to as drops, are used over the interior columns, half drops are required at the exterior columns. Beams are used to frame around stairwells and elevators, and as lintels connecting exterior columns.

½ Column Strip

Fig. 13

For purposes of establishing the bending moments and the resisting moments of a square panel, the panel is divided into middle and column strips as shown in Fig. 13. In this figure the division is indicated in only one direction, but a similar division is also made at right angles to the strips shown.

The diameter of the column capital is usually taken as 0.225 × average center-to-center span of bay. The minimum width of drop is taken as 0.33 or 0.35 × length of span in that direction; except for heavy loads the shearing stresses around the perimeter of the drop are not excessive, and this requirement normally determines the dimensions of the drop. The offset, or difference in thickness between the slab and drop, varies from 2 to 4 in. It is usually controlled by the sectional area required over the column capital to resist the negative moment on the column strip. In computing this depth it is usual to allow an increase of 15 per cent in the value of the extreme fiber stress f_c, as with beams.

The bending moments used in designing the various sections are derived from empirical data and form a part of the code requirements in all city ordinances. Those used in the example are from the Joint Standard Building Code; they apply to fully continuous interior bays. The moments are generally increased by 20 or 25 per cent along the center lines of exterior bays and over the first interior supports. At the wall, or spandrel, the negative moment in the column strip is taken as 80 or 90 per cent and in the middle strip as 50 or 62.5 per cent of the corresponding moments for a normal interior panel. Half bands, containing 50 per cent of the steel required for a column strip, are placed parallel to the outer edge of exterior panels. The spacing of rods is limited to $1\,{}^{1}/_{2}$ × slab thickness, and the ratio of steel to concrete area in any strip should not be less than 0.0025.

There are two widely used systems of reinforcement, the two-way and the four-way. In the former, bands of steel rods are designed to span from column to column, and a two-way reinforcement is placed in the central rectangular portion of the panel between the bands and running parallel to them. In the four-way system, two diagonal bands supplement the direct bands, and additional reinforcement is added in the form of short rods placed over the lines of support, perpendicular to the steel of the rectangular bands.

Practically every large city has its own individual code governing the design of girderless floors, and when working under any particular jurisdiction, the designer must apply the regulation in his locality. The following example is based upon common practice and corresponds to the average requirements of principal cities. It will be noted that the thickness of the slab, size, and depth of drop are each controlled by several criteria. Where it is possible to satisfy the design requirements in more than one way, the most economical method is shown.

Example. Required: to design an interior bay sustaining a superimposed load of 150 lb per sq ft. Drops and a two-way reinforcement will be used. Dimensions center-to-center columns, 20 × 20 ft. Specification data: $f_c = 650$; $f_s = 18{,}000$; allowable unit shearing stress (v_1) around perimeter of drop = 60 lb per sq in.; allowable unit shearing stress (v_2) around perimeter of column capital = 120 lb per sq in.

Slab thickness not less than

(1) $t = 6$ in. (a minimum often specified).

(2) $t = L/32 = 20/32 = 0.625$ ft $= 7\,{}^1/_2$ in., where t = total thickness of slab, inches; L = center-to-center span between columns on long side of panel, feet.

(3) $t = 0.02L\sqrt{w} + 1 = 0.02 \times 20\sqrt{244} + 1 = 7.25$ in., where w = the superimposed load, 150 lb per sq ft, plus the estimated weight of the slab, 90 lb per sq ft, plus estimated weight of drop, 4 lb per sq ft, distributed over the entire slab.

Accept a slab thickness of $7\,{}^1/_2$ in.

Width of drop (b) not less than $0.35L = 0.35 \times 20 = 7$ ft.

Vertical shear around perimeter of drop, $V = w(L^2 - b^2) = 244\{(20)^2 - 7^2\} = 85{,}644$ lb, where L^2 = area of bay, b^2 = area of drop. By formula 17, $v = V/(bjd) = 85{,}644/(4 \times 84 \times 0.875 \times 6) = 48$ lb per sq in., where (4×84) = the perimeter of drop, and 6 = effective depth of slab. As 60 lb per sq in. is permitted, accept a square drop, with side of 7 ft 0 in.

Diameter of column capital $c = 0.225L = 0.225 \times 20 = 4$ ft 6 in. = 54 in.

Total thickness of slab and drop not less than, by formula 4,

$$d = \sqrt{M/Kb} = \sqrt{767{,}200/(125.7 \times 84)} = 8.53,$$

where M = bending moment, pound-inches, at column head section as computed below by the equation $M = WL/30.5$. Value of K from Table IV. Assume a total thickness of 10 in., effective depth $8\,{}^1/_2$ in.

Vertical shear around perimeter of column capital,

$$V = w(L^2 - ({}^1/_4)\pi c^2) = 244\{(20)^2 - 0.7854 \times (4.5)^2\} = 93{,}700 \text{ lb.}$$

$$v = V/(bjd) = 93{,}700/(54\pi \times 0.875 \times 8.5) = 74 \text{ lb per sq in.}$$

Since 120 lb per sq in. is permitted, a total thickness of 10 in. is acceptable. This gives an offset at the drop of $2\,{}^1/_2$ in.

Steel areas as controlled by moments:

$$W = \text{total load on bay} = (20 \times 20 \times 240) + (7 \times 7 \times 30) = 97{,}500 \text{ lb}$$

Column strip,

$$-M = Wl/30.5 = 97{,}500 \times 20 \times 12/30.5 = 767{,}200 \text{ lb-in.}$$

$$+M = Wl/77 = 97{,}500 \times 20 \times 12/77 = 303{,}900 \text{ lb-in.}$$

Middle strip,

$$-M = +M = Wl/102.5 = 97{,}500 \times 20 \times 12/102.5 = 228{,}300 \text{ lb-in.}$$

in which l = length, inches, between column centers in the direction in which the strip extends. The bending moment factors used in this example are from the Joint Standard Code.

Column strip:

Negative reinforcement,

$$A_s = \frac{M}{f_s jd} = \frac{767{,}200}{18{,}000 \times 0.872 \times 8.5} = 5.73 \text{ sq in.}$$

Positive reinforcement,

$$A_s = \frac{M}{f_s jd} = \frac{303{,}900}{18{,}000 \times 0.883 \times 6} = 3.19 \text{ sq in.}$$

Middle strip, both positive and negative reinforcement,

$$A_s = \frac{M}{f_s jd} = \frac{228{,}300}{18{,}000 \times 0.883 \times 6} = 2.39 \text{ sq in.}$$

For the column strip, accept 11 ${}^5/_8$-in. rounds each way, which satisfies the requirement of the positive moment. Raise 7 of these rods from each bay along the line of inflection, $0.3(L - c) = 0.3(20 - 4.5) = 4.65$ ft, from center of span, which gives a steel area of 4.20 sq in. The additional area = 1.53 sq in., necessary for the negative reinforcement, is furnished by 5 ${}^5/_8$-in. rounds placed over columns and extending 1 ft beyond lines of inflection. The 4 remaining rods in the bottom of the slab are extended into the drop panel a distance of 1 ft. For the middle strip, accept 12 ${}^1/_2$-in. rounds each way, which satisfies the requirement of the positive moment within 5 per cent. Raise 6 of these rods from each bay along the line of inflection, $0.3l$ from center of span, which gives a steel area equal to that at mid-span. The 6 remaining rods, in the bottom of the slab, are extended 20 diameters each side of the lines of inflection. The bent rods of both strips, in both directions, are extended entirely across the bay and to 1 ft beyond the lines of inflection of adjacent bays.

Table XI gives the dimensions and reinforcement for girderless floor construction of the square-panel, two-way reinforcement type, based on the New York City code.

Table XI. Dimensions and Reinforcement for Girderless Floor Construction, Square Panels, Two-Way System

Fiber stresses. $f_s = 16{,}000$, $f_c = 650$, $v_1 = 60$, and $v_2 = 120$ **lb per sq in. All reinforcing steel, round bars.** Based on New York City Code.

TESTING OF MATERIALS

By Jasper O. Draffin

33. EQUIPMENT

Testing Machines. Machines for testing material are of varying construction and capacity, for testing specimens in tension, in compression, in torsion, and for other specific purposes. In machines for testing bars in tension or compression, the ends of the test piece are fastened in the two heads of the machine. One of the heads is moved by screws, driven by a train of gears, causing a gradually increasing stress in the test piece. Some machines are built so that the head is moved by hydraulic pressure, but the screw construction is more common in the United States, although the use of hydraulic pressure machines is increasing rapidly (1935). Usually the mechanism for applying the load to the specimen is independent of the weighing apparatus. With this arrangement the accuracy of the weighing is not affected by the deformation of the specimen which takes place as the load is applied.

The Compound Lever Machine derives its name from the weighing mechanism. The load may be applied by revolving screws or by hydraulic pressure.

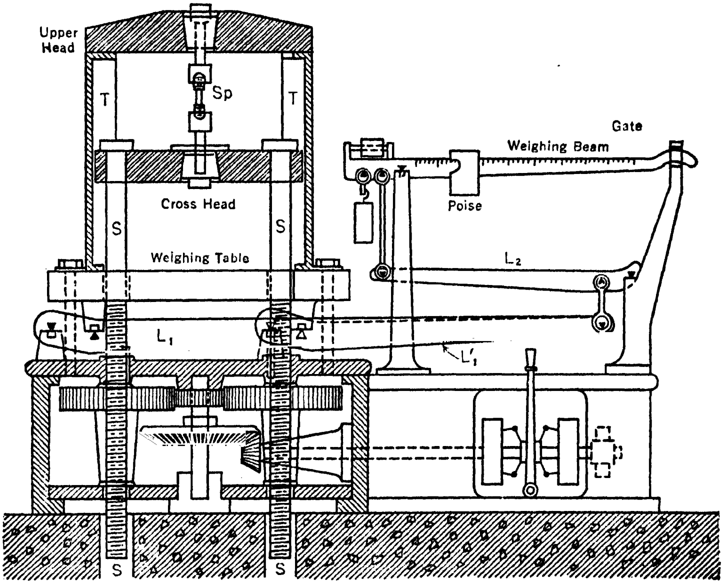

Fig. 1. Screw-power, Compound-lever Testing Machine

The Screw-power Compound-lever Testing Machine (Riehlé or Olsen Machines) is the type in most common use in the United States, and it is shown in diagram in Fig. 1. Power is supplied by a belt drive or by a direct-connected motor, and the power is transmitted through a series of gears to vertical screws which operate the crosshead of the machine. The force applied by the belt is multiplied many times by the gearing and the screws. This multiplied force is applied to the test specimen by the crosshead. If the specimen is a tension specimen it is placed between the crosshead and the upper head of the testing machine, if it is a compression specimen or a cross-bending specimen it is placed between the crosshead and the weighing table. In any event as the crosshead moves downward the specimen transmits downward pressure to the weighing table. The weighing table is supported on compound levers, $L_1L'_1$, Fig. 1, which are fitted with knife-edge bearings, and these compound levers transmit the force, reduced, to a simple lever, L_2, Fig. 1, which, in turn, transmits the force, still further reduced, to the weighing beam.

As load is applied the beam is kept in balance by moving the poise, the position of which indicates the load on the specimen, when the beam is in balance.

The Direct-acting Hydraulic Machine has a head moved by hydraulic pressure, the intensity of which is read on a pressure gage. The load on the test piece is determined by multiplying the pressure reading by a constant which depends on the area of the cylinder. Owing to variations in the plunger friction, these machines are not adapted for accurate testing of small specimens, but are used to advantage in tests requiring big loads to rupture the specimen, and where slight variations in accuracy are permitted.

The Amsler Machine is a machine of the hydraulic type built in Schaffhausen, Switzerland, which has a considerable use in the United States. A plunger moving in a cylinder near the top of the machine raises and lowers a rigid framework with respect to a fixed tension head at the bottom and a fixed compression head at the top of the machine. Oil is pumped into the cylinder to move a plunger so carefully ground to fit the cylinder that no packing is necessary. The error due to friction is no larger than the error due to friction in knife-edge lever weighing devices. The pressure is measured by the load on a small piston which moves a pendulum so that the position of the pendulum bob indicates the force. This is a self-indicating weighing device, which eliminates much of the personal equation of balancing a weighing beam. The Amsler testing machine can be handled by a single observer, even when measurements of deformation are made, and is very rapid in its operation.

The Emery-Tatnall Machine is a hydraulic machine in which the load is applied through a plunger moving in a cylinder under oil pressure. The distinctive feature is the load-weighing device, called a weighing capsule. This is not connected to the load-applying mechanism, and is unaffected by friction between cylinder and plunger. One of the testing heads rests on a thin flat diaphragm over a shallow recess filled with oil. A slight movement of the diaphragm decreases the volume of the recess and creates pressure on the oil, which is recorded on a gage calibrated to read the load. One precaution is necessary: the weighing capsule must be kept filled with oil to avoid recorded loads being seriously in error.

Verification of Tension-Compression Testing Machines. The A.S.T.M. Tentative Standard, E4-34T, *Proc. A.S.T.M.* vol. xxxiv, Pt. 1, p. 1233, 1934, lists the following four methods of verifying testing machines, in the order of their accuracy:

1. Standard Weights are placed on the weighing mechanism of the testing machine. This is the most accurate method but has the following limitations: (*a*) only a limited range of load can be covered; (*b*) the non-portability of standard weights; (*c*) the non-applicability to horizontal testing machines.

2. Proving Levers. These are simple levers with the fulcrums bearing on the weighing platform while knife-edges on the short arms of the levers bear on the crosshead of the machine. At the ends of the long arms of the levers, standard weights are hung so that from the ratio of the arms the force acting on the weighing table may be computed. Though the range of load possible with this method is greater than that of the standard weights method, it is not great enough for very large testing machines. The transportation of large proving levers and standard weights is inconvenient.

3. Elastic Calibration Device. An elastic calibration device consists of an elastic member which has previously been calibrated by noting the deformation at a series of loads. For a primary standard, the loads should be obtained by dead weights or proving levers (see A.S.T.M., *loc. cit.*). When verifying a testing machine, load is applied to the device by the machine to be tested and the deformation noted. The difference between the load reading on the machine under test and the actual load, as determined for the observed deformation from the calibration curve of the device, represents the error in the machine being verified.

4. Comparison Method. In this method, a series of test specimens ("companion specimens") cut from the same piece of metal are necessary. Half of the specimens are tested in a machine which has been verified by one of the other methods above, and the other half in the machine under test. The difference in load reading for the same deformation, between the two machines, is the error in the machine being tested. This method should be used only when none of the other methods above may be applied.

Accuracy and Sensitivity of Testing Machines are two distinct characteristics. A machine is accurate if the readings of the machine agree closely with the actual loads applied by the machine. A testing machine is sensitive if a small change of load is indicated by a distinct movement of the beam or other weighing mechanism. A testing machine may be very sentitive, and yet very inaccurate.

For Flexure Tests the regular tension-compression testing machines are used by arranging the specimen so that the end supports bear on the weighing table, as shown in Fig. 7, p. 5-86.

Torsion Testing Machines. In Professor Thurston's machine, invented in 1872, the specimen is held horizontally with its ends secured in two spindles. One of these spindles is rotated by power. The other spindle is connected to a pendulum carrying a heavy weight which resists the turning force as it deviates from its vertical position, thus producing a torque whose magnitude is shown by a gage or dial.

Power torsion machines are built so that the two ends of the specimen are held in rotating chucks. The power is applied at any desired speed by gearing connected to one of the chucks. The chuck at the other end is prevented from rotating by a system of levers connected to a scale beam which is balanced by a poise. The position of the poise indicates the twisting moment in pound-inches.

For Impact Tests the essential parts of the testing machine are: a moving weight which strikes the specimen with sufficient kinetic energy to cause fracture, an anvil or block on which the specimen is supported and a device for measuring the kinetic energy of the moving weight after it has broken the specimen.

In the Drop-weight Machines the impact is obtained by a hammer of known weight falling from a predetermined height on the specimen. In the Fremont machine the loss of kinetic energy in the hammer due to impact is obtained by having the weight, after breaking the specimen, strike a platen placed on calibrated springs, and measuring the downward movement of the platen against the resistance of the springs. Another method is used in the Hatt-Turner machine in which a brass stylus is attached to the falling hammer; during impact the stylus is forced by a spring against a sheet of metallized paper mounted on a drum which rotates about its vertical axis, thus causing a curve to be plotted. The speed of the drum is determined from a second curve plotted on the metallized paper by a stylus fastened to one prong of a tuning-fork. From the two curves the changes in velocity of the hammer as well as the stress-deformation relations may be calculated.

The Charpy Impact Testing Machine is used for tests of small specimens of metal under impact. The specimen rests against the vertical face of an anvil where it is held in a horizontal position and is in flexure over a short span. The impact is furnished by a pendulum which is let fall from a predetermined height, striking the specimen at the bottom of its swing. The pendulum is of known weight, and is so hung that its center of percussion is at the point of impact against the specimen. After breaking the specimen the pendulum continues its swing, and an indicating apparatus shows the maximum height to which it rises. The energy supplied by the pendulum is the product of its weight and its height of fall; the energy left after the fracture of the specimen is the product of its weight and the height of rise; the difference is the energy required to break the specimen. Specimens for the Charpy machine are notched at the middle of their length to insure a sharp plane of fracture. The uniformity of size of specimen and of size and shape of notch is very important.

The Izod Machine acts on a principle similar to that of the Charpy machine. The Izod specimen is a short notched cantilever beam held vertically and struck by a swinging pendulum, at a definite distance above the notch. The energy required for fracture is measured in a manner similar to that used with the Charpy machine.

Repeated Stress Testing Machine. The following types of machines are available for producing reversed bending: the Upton-Lewis for flat specimens; the short-specimen rotating beam; the long-specimen rotating beam; and the cantilever rotating beam. Only the long-specimen machine (sometimes known as the Sondricker or Farmer type) is here described. It consists of two supporting rings or collars, rotating in a cage of ball bearings, for supporting the specimen which is 0.40 in. in diameter and 13 in. long. The specimen is rotated by a motor; the number of revolutions is recorded by a counter attached to one end of the specimen. Suspended weights load the beam at two points and act through ball bearings to produce a uniform bending moment over the central portion of the specimen. The number of cycles of completely reversed stress equals the number of revolutions. The speeds commonly used are from 1000 to 2000 rpm.

Extensometers are used for measuring the small elastic deformations within the elastic limit, and for detecting the stress at which the elastic limit is exceeded. An extensometer consists essentially of two clamps which are fastened to the test specimen, and one or more micrometer devices by means of which a very small change of distance between the clamps can be measured. For all accurate measurement of elastic deformation of tension or compression specimens the extensometer should be attached so as to measure deformation along two or three symmetrically spaced axial lines on the specimen. Types of micrometer devices used in extensometers are: the screw micrometer, in which a very small axial motion of a screw is accompanied by a large circumferential motion of a dial attached to the screw; clockwork dial gages; multiplying levers; microscopes; and the "optical lever" in which a very small angular motion of a mirror changes the direction of a reflected ray

of light. Extensometers for general use usually measure deformations to the nearest ten-thousandth of an inch.

34. STANDARD TEST SPECIMENS

Specimens for Tension Tests of Wrought Metals. (Abstracted from A.S.T.M. Standards E8–33, A7–34, A9–34 and A10–34.) The specimen shown in Fig. 2 is recommended for plate, shape, and flat material having a thickness of $^1/_4$ in. or over. The thickness of the specimen shall be that of the material tested.

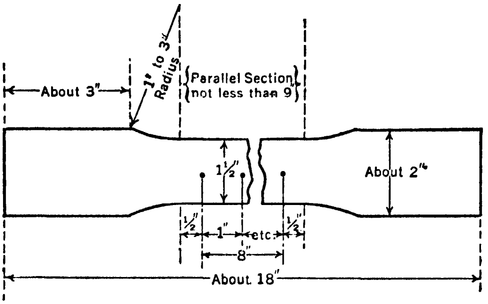

Fig. 2. Standard 8-in. Gage Length Test Specimen

If the material to be tested is over 1 $^1/_2$ in. in thickness or diameter, except steel pins or rollers, it may be machined to a thickness or diameter of at least $^3/_4$ in. for a length of at least 9 in., or it may conform to the dimension shown in Fig. 3. Specimens for pins and rollers should conform to the dimensions of Fig. 3.

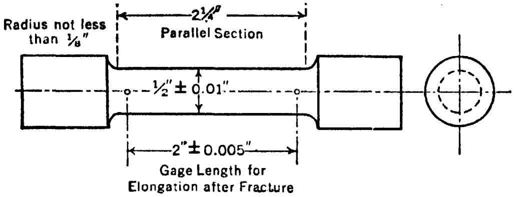

Fig. 3. Standard 2-in. Gage Length Tension Test Specimen

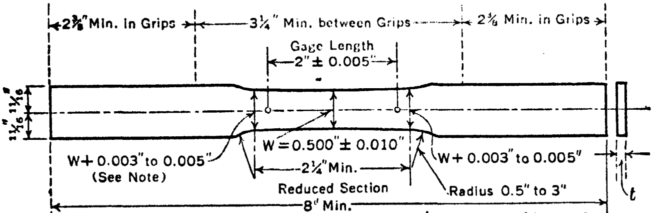
The specimen shown in Fig. 3 is recommended for general use in testing metals. The gage length, parallel section and fillets should be as shown, but the ends may be of any shape to fit the holders of the testing machine in such a way that the load is axial.



Note: Gradual Taper from Ends of Reduced Section to Middle.

t = Thickness of Material

All machining dimensions are shown below and testing dimensions above specimen.

Fig. 4. Standard Tension Test Specimen for Sheet Metals

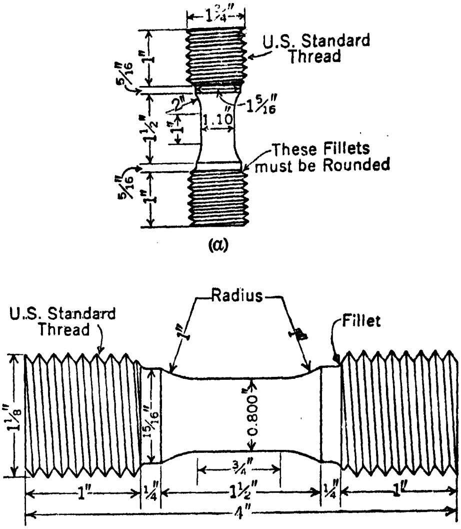
A slight taper of the " parallel section " not to exceed a maximum of 1 per cent of the diameter within the gage length, similar to that shown in Fig. 4 for sheet materials, is desirable for all tension test specimens.

Steel specimens should be prepared for testing from the material in its rolled or forged condition except that annealed materials should be annealed as for use.

For tension tests of wrought ferrous and non-ferrous metal in the form of plate, sheet, flat wire, strip, band and hoop, without respect to width (provided the width is not less than that shown in Fig. 4), length, grade or method of manufacture, and having a thickness of from 0.01 to 0.250 in., the specimen shown in Fig. 4 is recommended.

Tension test specimens of wire and rod are frequently of the full size as fabricated. It is suggested that the upper limit of size for wire be considered as 1/2 in. in diameter. For the measurement of elongation of wire or rod 1/2 in. in diameter or less which is tested in the full size, a gage length of 10 in. is frequently used.

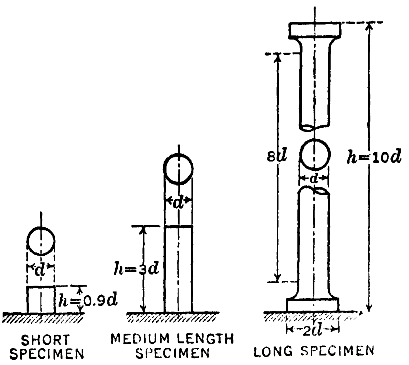
Specimens for Tension Test of Cast Iron. Tension test bars for cast iron are classified according to the controlling thickness of the casting as: test bar *A*, thickness 0.75 in., maximum; test bar *B*, thickness 0.75 to 1.25 in.; test bar *C*, thickness 1.25 to 2.00 in. (*Proc. A.S.T.M.*, vol. xxxii, Pt. I, p. 625, 1932). It is optional to use parts of the transverse test bar for the tension test. Dimensions of the finished specimens for test bar *B* are shown in Figs. 5*a* and 5*b*.



(*a*) (*b*)

Fig. 5

Specimens for Compression Tests of Metals. (Abstracted from *A.S.T.M. Tentative Standards*, 1934, E9-34T.) The following three classes of compression test specimens are recommended: (1) short specimens (Fig. 6*a*), used for tests of such metals as bearing metals, which in service are used in the form of a thin plate or shell to carry load perpendicular to the surface; (2) medium-length specimens (Fig. 6*b*), used for determining the general compressive strength properties of metallic materials; (3) long specimens (Fig. 6*c*), best adapted for determining the modulus of elasticity in compression of metallic materials. In reporting the results of a compression test, it is important that the dimensions of the test specimens be given.



SHORT SPECIMEN (*a*) MEDIUM LENGTH SPECIMEN (*b*) LONG SPECIMEN (*c*)

Fig. 6. Test Specimens for Compression Tests

The suggested dimensions for the compression specimens shown in Fig. 6 are as follows.

	Diameter, *d*	Height *h*
Short specimens	1 1/8 in.* ± 0.01 in.	1 in.
Medium-length specimens	0.798 in. ± 0.01 in. 1 in. ± 0.01 in. 1 1/8 in. ± 0.01 in.	2 3/8 in. 3 in. 3 3/8 in.
Long specimens	1 1/4 in. ± 0.01 in.	12 1/2 in.

---

* Area of cross-section is approximately 1 sq in.

Specimens for Flexure Tests of Cast Iron. Until 1932 gray iron castings were classified as light, medium, and heavy according to thickness, and acceptance was based

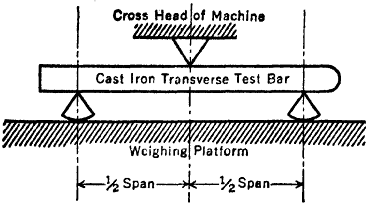


Fig. 7

on flexure or transverse tests. This specification has been revised, and A.S.T.M. Standard, A48–36 specifies acceptance on tension tests. Transverse tests are optional and are made with the machine shown in Fig. 7 on straight, cylindrical specimens having the dimensions and tested with the spans listed in Table I. The first three numbers refer to ordinary gray iron and the last four numbers to high-strength iron.

Table I. Test Specimens for Transverse Tests

Class	Minimum Tensile Strength, lb per sq in.	Test Bar *	*A*	*B*	*C*

35. METHODS OF TESTING

Determination of the Yield Point. See also p. 5–04. The following two methods are satisfactory for determining the yield point of metals that have a " sharp kneed " stress-strain or stress-deformation diagram:

1. The " Drop of the Beam " Method. Load is applied to the specimen at a steady rate of increase and the operator keeps the beam in balance by running out the poise. At the yield point the increase of load ceases temporarily, but the operator, running out the poise at a steady rate, runs it a trifle beyond the balance position, and the beam of the machine drops for a brief but appreciable interval of time. In a machine fitted with a self-indicating weighing device there is a sudden halt in the motion of the load-indicating pointer, corresponding to the drop of the beam. The load at the " drop " or the " halt " is noted and the corresponding unit stress reported as the yield point.

2. Total Deformation Method Using Dividers. An observer with a pair of dividers watches for visible elongation between two gage marks on the specimen. When visible stretch is observed the load is noted and the corresponding unit stress reported as the yield point.

Determination of Yield Strength. For determining the yield strength, the following two methods are given by the A.S.T.M. Standards, 1933, E8-33.

1. The Set Method. This method can be used, if desired, for materials having sharp-kneed stress-strain diagrams but is especially adapted to materials whose stress-strain diagram in the yield range is a smooth curve of gradual curvature.

For nearly all materials, if at any point on the stress-strain diagram, such as r in Fig. 9, the load is released, the diagram for decreasing load will follow a line, rm, approximately parallel to the initial portion, OA, of the diagram for increasing load. Om will then give the approximate value of the permanent set after the release of the stress OR. The value of this set is given in percentage of original gage length. Thus, to determine the yield strength by the " set method," it is necessary to secure data (autographic or numerical) from which a stress-strain diagram may be drawn. Then with the stress-strain diagram (Fig. 9) lay off Om equal to the specified value of the set, and draw mn parallel to OA and thus locate r, the intersection of mn with the stress-strain diagram. Draw Rr parallel to the X-axis, and then OR gives the value of the yield strength.

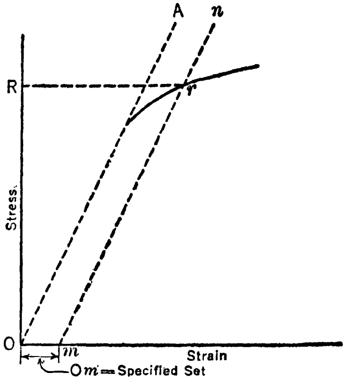

FIG. 9. Stress-strain or Stress-deformation Diagram

In reporting values of yield strength obtained by this method, the specified value of " set " used should be stated in parentheses after the term yield strength. Thus:

Yield strength (set = 0.1 per cent) = 52,000 lb per sq in. indicates that, at a stress of 52,000 lb per sq in., the approximate permanent set of the material reached the value of 0.1 per cent of the original gage length. (A value of 0.20 per cent of the gage length has been used rather widely for metals.)

In using this method, an extensometer reading to 0.0001 in. per in. of gage length would be sufficiently sensitive for most materials. It will be observed that the elastic limit and proportional limit are special values of the yield strength, in which the specified limiting set is not measurable with the instruments used, and hence is considered to be zero.

2. Approximate Method without Stress-strain Diagram. For tests to determine the acceptance or rejection of material, whose stress-strain characteristics are well known from previous tests of similar material in which stress-strain diagrams were plotted, the total strain corresponding to the stress at which the specified permanent set occurs will be known within satisfactory limits; therefore, in such tests a specific total strain may be used, and the stress on the specimen, when this total strain is reached, is the value of the yield strength. The total strain can be obtained satisfactorily by use of an extensometer, or in some cases by use of dividers, particularly if the surface of the specimen is prepared so that the line made by the dividers is a fine line, and if it is observed through a reading glass. But it is recommended that this approximate method be used only after agreement between producer and consumer, with the understanding that check

tests be made for obtaining stress-strain diagrams for use with the Set Method to settle any misunderstandings.

Determination of Tensile Strength (Ultimate). The tensile strength of a material is determined by dividing the maximum load carried in a tension test by the original area of cross-section of the specimen. It is important that the speed of testing should not be so high as to render uncertain the balancing of the beam of the testing machine, or to cause "surging" of the indicating mechanism of a self-indicating load-measuring device.

Determination of the Elongation after Fracture (from A.S.T.M. Standards, 1933, E8–33). The measurement of the elongation after fracture of tension test specimens can be made with sufficient accuracy by means of a pair of dividers and a scale. The elongation should not be reported for any tension test specimen which breaks outside the middle third of the gage length.

NOTE. If only a few specimens are furnished for testing, it is recommended that, in marking the gage length for measuring elongation after fracture, it be divided into eight parts (as shown in Fig. 10), and that, if a specimen breaks inside the gage length but outside the middle third of the gage length, the requirement in the foregoing paragraph be waived, and the elongation be measured and reported as follows:

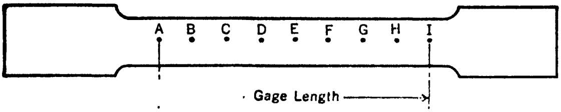

FIG. 10. Method of Marking Gage Length for Measuring Elongation after Fracture

1. If the specimen breaks in the middle half of the gage length (between C and G), the elongation is measured directly over the stretched gage length.
2. If the specimen breaks between A and C (or between G and I) but nearer B than A (or nearer H than I), the elongation from A to C (or from G to I) is measured, and to this is added *twice* the measured elongation from C to F (or from D to G).
3. If the specimen breaks within one-half a division of an end gage mark, the elongation from A to E (or from E to I) is measured and multiplied by 2.

The above method can be applied to specimens of any gage length, and to turned specimens as well as flat specimens.

This method is not applicable to brass specimens.

Determination of Reduction of Area. The measurement of reduction of the dimensions of a specimen after fracture may be made by the direct measurement with a micrometer of the smallest cross-section of the specimen. For round specimens this measurement can best be made by holding the broken pieces together in a vise or between centers and then measuring the average diameter of the smallest section by means of a micrometer fitted with rather sharp points. The reduction in area is calculated as the percentage reduction, based on the original area.

Owing to the difficulty of making accurate measurements of the fractured area of a test piece and to the fact that elongation is more valuable than reduction of area as a measure of ductility, of toughness, or of energy absorbed before rupture, reduction in area frequently is not reported.

Compression Test. The methods used for determining elastic limit, proportional limit, yield point, and yield strength in compression tests are, in general, the same as those used in tension tests. The compressive strength is determined by dividing the maximum load by the original area of cross-section of the specimen.

In a material which fails in compression with a shattering fracture the compressive strength has a very definite value. In materials which do not fail by a shattering fracture the value obtained for compressive strength is an arbitrary value depending on the degree of distortion which is regarded as indicating complete failure of the material.

Precautions Required in Making Tests

1. Inspection of Specimen. Examine the specimen for defects or irregularity of form.

2. Placing Specimen in Machine. The test piece should be placed in an axial position, that is, the line of stress of the machine should be in line with the axis of the specimen. Care should be taken to see that the ends of the specimen are properly gripped in the heads of the machine. When wedges are used, the full length of the wedge should bear against the ends of the specimen. The extensometer should be placed in position so that the clamps are at the gage marks and the specimen centered in the instrument.

3. Speed of Testing. Regard must be had to the time occupied in making tests of certain materials. A.S.T.M. Standard, E8-33, points out that the values of the yield point and ultimate strength may be increased by operating the testing machine at too high speed, and it recommends that the speed of the head of the testing machine shall be such that the load can be accurately weighed. In determining yield strength, the crosshead speed for the 2-in. gage length shall not exceed 0.125 in. per min.

In testing soft alloys, copper, tin, zinc, and the like, which flow under constant stress, their highest apparent strength is obtained by testing them rapidly. In recording tests of such materials the length of time occupied in the test should be stated.

4. Increment of Load. The following method has been suggested by the A.S.T.M. (*loc. cit.*) for choosing increments in a tension test. An increment of load, about $^1/_{10}$ of the estimated load corresponding to the knee of the stress-deformation diagram, is applied and the corresponding change of reading, Δ, of the extensometer noted. For the remainder of the test, the increments of load are made such that the extensometer readings change by approximately Δ.

After the yield point is passed, as indicated by the drop of the beam, the stress should be uniformly increased, keeping the scale beam balanced and stopping only to make occasional observations and to remove the extensometer to prevent its injury when the specimen breaks.

36. MISCELLANEOUS TESTS

Hardness Tests

Brinell's Method. J. A. Brinell, a Swedish engineer, in 1900 published information about a method for determining the relative hardness of steel, which has come into extensive use. A hardened-steel ball, 10-mm diameter (0.3937 in.), is forced with a pressure of 3000 kg, or 500 kg for soft metals, into a flat surface on the sample to be tested and allowed to remain for at least 10 sec (iron and steel), or for at least 30 sec (other metals), to make a slight spherical impression, whose diameter is measured with a microscope. The hardness is defined as the quotient of the pressure divided by the area of the surface of the impression, which is assumed to be spherical. From the measurement, the *hardness number* is calculated by the equation

$$B = \frac{P}{\pi \frac{D}{2} (D - \sqrt{D^2 - d^2})} \tag{1}$$

where P = load = 3000 kg; D = diameter of ball = 10 mm; d = diameter or width of impression, millimeters; B = Brinell hardness number. Table II gives the hardness numbers corresponding to the different values of d. A complete table of these numbers is given in A.S.T.M. Standards, 1933, E10-27, pp. 943-944.

There is a well-defined approximate relationship between the Brinell numbers and the ultimate strength of steel. Abbot (*Proc. A.S.T.M.* vol. xv, Pt. II, 1915), as a result of a large number of tests of different kinds of steel, proposed the equation $s_u = 0.70B - 26$, where s_u = ultimate strength in thousands of pounds per square inch; B = Brinell hardness number. For many steels, however, the strength is as well represented by the relation $s_u = 0.50B$.

In the Rockwell Test a steel ball $^1/_{16}$ in. in diameter (the Rockwell " B " test) or a conical diamond point (the Rockwell " C " test) is pressed against the surface of the specimen with a small but definite initial load. Then a load of 100 kg (" B " test) or 150 kg (" C " test) is applied by means of a weight acting at the end of a compound lever. This weight is removed, leaving the small initial load still on the penetrating point, and the depth of impression is measured by means of a micrometer dial gage attached to the indenting point. This gage is graduated to read directly an arbitrary system of hardness numbers corresponding (inversely) to the depth of impression. The Rockwell " B " numbers are different from the Rockwell " C " numbers. One advantage of the Rockwell over the Brinell is that a smaller indentation is produced. The ultimate tensile strength of steel, s_u, is given in thousands of pounds per square inch by the equation $s_u = 3750/(130-R_B)$, R_B being the number ("B" test) read from the dial of the instrument.

The Vickers Pyramid Hardness-testing Machine is a British instrument in which the principle employed is the same as that in the Brinell and Rockwell machines. The operation differs in that the penetrator is a diamond in the form of a pyramid. By means of a microscope attachment, measurements are made of the distance across the diagonal of the indentation. One of the advantages of this machine is that it is suitable for any degree of hardness.

The Scleroscope is an instrument invented by A. F. Shore for determining the hardness of metals. It consists chiefly of a vertical glass tube in which slides freely a small cylinder of very hard steel, pointed on the lower end, called the hammer. This hammer is allowed to fall about 10 in. onto the sample to be tested. The distance it rebounds is taken as a measure of the hardness of the sample. A scale on the tube is divided into 140 equal parts, and the hardness is expressed as the number on the scale to which the hammer rebounds. Measured in this way the hardness of different substances is as follows: glass, 130; porcelain, 120; hardest steel, 110; tool steel, 1 per cent carbon, may be as low as 31; mild steel, 0.5 C, 26 to 30; gray iron castings, 39; wrought iron, 18; babbitt metal, 4 to 10; soft brass, 12; zinc, 8; copper, 6; lead, 2 (*Cass. Mag.*, Sept., 1908). The relationship between the scleroscope number and the ultimate tensile strength, s_u, is given by Abbott (*loc. cit.*) by the equation $s_u = 4.0S - 15$, where s_u is in thousands of pounds per square inch and S is the scleroscope number.

Moh's Scale of Hardness is commonly used in testing the hardness of rocks and minerals. Hardness is recorded in terms of the following scale: 1, talc; 2, gypsum; 3, calc spar; 4, fluor spar; 5, apatite; 6, feldspar; 7, quartz; 8, topaz; 9, sapphire; 10, diamond. A convenient test for the softer minerals is: Scratched by finger-nail, up to hardness of 2.5; by copper coin, up to hardness of 3; by knife-blade, up to hardness of 5.5.

Some smooth surface of the mineral to be tested is selected, on which a point of the standard is pressed and moved back and forth several times $1/8$ in. or less. If the mineral is scratched it is softer than the standard. Two minerals of equal hardness will scratch each other. Pulverulent or splintery minerals are "broken down" by the test and

Table II. Conversion Table for Approximate Hardness Numbers Obtained by Different Methods

yield an " apparent " hardness often much lower than the true hardness. Rough surfaces also yield doubtful results.

Relationship between the Different Hardness Numbers. A rational relation exists between the Brinell and Rockwell numbers, and also between these numbers and the Vicker's pyramid numbers; an empirical relation exists also between the foregoing numbers and those of the Shore scleroscope. Petrenko (Tech. Paper 334, U. S. Bur. Standards) gives the following equations:

$$B = 25{,}000/(100\text{-}R_C) \text{ for } R_C \text{ greater than } 40$$

$$B = 1{,}420{,}000/(100\text{-}R_C)^2 \text{ for } R_C \text{ from } -20 \text{ to } 40$$

$$B = 7300/(130 - R_B) \text{ for } R_B \text{ from } 35 \text{ to } 100$$

where B = Brinell number obtained with a 10-mm ball and 3000-kg load; R_C = Rockwell number on the C scale, using a 150-kg load and a 120° diamond penetrator; R_B = Rockwell number on the B scale with a 100-kg load and a $^1/_{16}$-in. ball.

Abbott (*Proc. A.S.T.M.*, vol. xv, Pt. II, 1915) derives from tests the empirical relation $B = 5.5S - 28$, B being the Brinell number and S the scleroscope number. Table II gives these various hardness numbers in terms of one another. The values were obtained from the manufacturers of the instruments and from published experimental data. The scleroscope numbers, as tabulated, vary slightly from those given by the Sub-Committee on Hardness Conversion of the A.S.S.T. in its 1930 handbook; the committee gives a scleroscope value of 81 for a Brinell number of 627 as compared with 84 in Table II (by interpolation), whereas the committee scleroscope number is 30 for a Brinell number of 197 as compared with 28 in Table II. Both lists are the same for scleroscope number 54 which equals Brinell number 387.

Ductility Tests

Ductility as Determined from Tension Test. The usual measures of ductility are the percentage of elongation and the percentage of contraction of area of a specimen in a tension test. Since the percentage elongation varies widely over the length of a tension specimen, the gage length over which the deformation is measured should be specified. A tension test for determining ductility is not suitable for many metals, for example, a thin metal specimen which in tension usually fails without any appreciable elongation.

Bending Test for Determining Ductility. The following is the A.S.T.M. Standards, 1934, A9-34, specification for bend tests on structural steel:

Bend test specimens shall stand being bent cold through 180° without cracking on the outside of the bent portion, around a pin, the diameter of which shall have the following relation to the thickness of the specimen:

Thickness of Material	Ratio: $\frac{\text{Pin Diameter}}{\text{Thickness of Specimen}}$
Up to $^3/_4$ in., inclusive	1
Over $^3/_4$ to 1 in., inclusive	$1\,^1/_2$
Over 1 to $1\,^1/_2$ in., inclusive	2
Over $1\,^1/_2$ to 2 in., inclusive	$2\,^1/_2$
Over 2 in.	3

Cupping Tests for Determining Ductility. For determining the relative ductility of thin sheet metal, the so-called cupping test is often used. There are various machines on the market for performing this test. In these, a spherical-ended plunger or ball is forced into the test specimen, which is held over a suitable die. For some machines, the maximum depth of the cup, inches, which can be formed, for others, the load required to produce the cup, just as visible " necking down " occurs, is taken as a measure of the ductility.

Short-time Tests for Endurance Limit

Short-time Tests for Endurance Limit. Since the determination of the endurance limit for any given steel or metal takes considerable time, attempts have been made to devise short-time tests which will give at least some indication of the probable endurance limit. No method has been found which is entirely satisfactory or which has been generally accepted. Two methods have shown some promise of success: (1) the rise-in-temperature method; (2) the electrical resistance method.

Rise-in-Temperature Method. (Moore and Kommers, *Bull.* 124, *Eng. Exp. Sta.*, Univ. of Ill., 1921.) A standard rotating beam specimen is held at one end and, by an eccentric movement of the other end, a bending stress is produced in a manner similar to that obtained when the beam is rotated. A thermocouple is attached to the specimen at the section of greatest stress and connected to a galvanometer. The specimen is run at 1000 rpm for 30 sec at stresses which increase by stages; a reading of the galvanometer is taken for each value of the stress. The stress at which there is a sudden increase in the reading of the galvanometer is taken as the endurance limit. For ferrous metals the results varied from 14 per cent below those found by the standard long-time method to 18 per cent above, but in the main they were within 5 or 6 per cent of the standard values. The test does not give consistent results with non-ferrous metals.

Electrical Resistance Method. This is sometimes known as the Ikeda method, after the Japanese who developed it. (See Moore and Konzo, *Bull.* 205, *Eng. Exp. Sta.*, Univ. of Ill., 1930.) It consists in determining the electrical resistance corresponding to various stresses and noting a sudden change in the resistance. The stress where the change occurs is taken as the endurance limit. The method gives results comparable with those obtained by the rise-in-temperature method and gives consistent results with non-ferrous metals. It requires delicate instruments and careful manipulation.

Creep Tests

Creep Limit Tests. The following description of the apparatus for and the method of making creep tests is abstracted from F. H. Norton's The Creep of Steel at High Temperatures, McGraw-Hill, New York, 1929. Specimens 0.505 in. in diameter with a 4-in. gage length are placed in an electric furnace. The load is applied by weights and a lever having a ratio of 10 to 1. The furnace, which holds 5 or 6 specimens at one time, is a hollow cylinder wrapped with asbestos paper and a heating coil which maintains a constant temperature through a regulating device. The extension of each specimen is measured by means of a dial connected to the lever arm which applies the load. To prevent oxidation of the specimen, a stream of nitrogen is introduced at the bottom of the apparatus.

The specimens are loaded nearly to the estimated creep limit for a given temperature, and this load is maintained for 400 hr, the elongation being measured twice a day. The load is then increased 10 per cent and maintained for 400 hr, the elongation again being measured twice a day, and this rate of increase in load is continued until the creep becomes large. Thus for each stress (at a given temperature) there will be a series of time-percentage elongation readings. A graph is plotted for each stress, with time as abscissa and percentage elongation as ordinate. This is usually a straight line. The slopes of these time-percentage elongation lines are next plotted against stress on logarithmic paper. There will be one line for each temperature and, since the points fall on a straight line, the stress corresponding to any given rate of creep for any given temperature may be read directly from the graph. Rapid progress is being made (1935) in the development and revision of standard methods of making short-time and long-time (creep) temperature tests. See A.S.T.M. Tentative Standard E22.

X-ray Inspection

X-ray Examination of Castings. When x-rays are passed through castings or forgings which contain defects, the x-rays pass through the defects more readily than through the sound metal and thus outline the defects on a photographic plate.

The x-ray examination of castings or forgings has two functions: (1) development of manufacturing technique; (2) inspection of the finished product. In Recommended Practice for Radiographic Testing of Metal Castings, A.S.T.M. Standards, E15–29, 1933, adopted 1929, the following defects are enumerated as being capable of detection by x-ray methods: gas cavities, slag inclusions, sand inclusions, pipe cavities, porosity, cracks, metal segregation. Since there are no standards governing the number, extent and character of defects, no specific requirement can be laid down, but if the defects are known to be present the user can judge of their probable effect and act accordingly.

Equipment. Equipment needed for x-ray examination consists of an x-ray tube, transformers, photographic apparatus, and a lead-lined operating chamber. The part to be examined is placed between the x-ray tube and the photographic film and an exposure made for the proper length of time. Since x-rays are very dangerous it is imperative that the operator be properly protected from them by lead-lined boxes or chambers. The operation is one requiring expensive apparatus and skilled technique, but it is very satisfactory for castings if a positive knowledge of their soundness is essential. For metal not over 3 1/2 in. thick, a 200-kv 8-milliampere Coolidge x-ray tube will be satisfactory. For detailed information see George L. Clark's Applied X-Rays. McGraw-Hill

Book Co., *Metals and Alloys*; St. John and Isenburger's Industrial Radiography, John Wiley & Sons, New York, 1934.

Special Tests

Proof Tests. A proof test is one in which a part of a machine or the machine as a whole is subjected to a load which equals or exceeds the allowable load but which does not test the part to destruction; for example, the hydrostatic test of cast-iron pipe at the foundry, where the pipe is subjected to a water pressure of about twice the normal working pressure.

Determination of Physical Properties from Magnetic Permeability. Tests of magnetic permeability of steel and iron seem to give some indication of the hardness, strength, and uniformity. They possess the great advantage that the test does not destroy the sample tested, and hence may be made on the actual parts to be used. Magnetic tests as an indication of hardness or strength are not standardized yet, but hold promise of future usefulness.

The variation of magnetic qualities in a bar or disk of metal has been used as a means of locating small invisible flaws. (See article by J. A. Capp, *Proc. A.S.T.M.*, vol. xxvii, Pt. II, p. 268, 1927.) This principle has been utilized in the construction of a special device, known as the transverse fissure detector car, for locating transverse fissures in railroad rails.

Special Tests of Materials, Structures, and Machines are often made. Table III gives some such tests.

Tests of Strength of Wood have not been standardized to an extent which allows their inclusion in specifications for timber, but compression tests, flexure tests, shearing tests, and impact tests are frequently made. Compression tests are made both along the grain and across the grain. Compression specimens are usually rectangular blocks, and

Table III. Special Tests of Materials, Structures, and Machines

Structural part, machine part, structure, machine or material tested	Test	Measurements
Floor panel of building.	Proof test with dead load, not to destruction.	Deflections, tensile and compressive deformations in beams and columns.
Bridge...............	Proof test with dead load or with moving load.	Deflections, tensile and compressive deformations in various members.
Riveted joints.........	Tests of samples to destruction.....	Ultimate load, slip of rivets.
Rivets, metal plates....	Shearing test of samples to destruction using special shearing tools.	Ultimate load, results depend on hardness of shearing tools used.
Bolts.................	Tests of samples to destruction in tension or torsion.	Ultimate load.
Boilers...............	Tests with hydrostatic pressure. Proof tests with pressures somewhat above working pressures.	Observation of leaks, cracks, or permanent distortion of parts.
Car couplers and coupler yokes	Proof tests, tests of samples to destruction under tension and impact tension.	Ultimate load, distortion under proof load.
Wire rope............	Tests of samples to destruction in tension.	Ultimate load, observation of manner of fracture.
Brake beams for railway cars.	Tests of samples to destruction in flexure.	Ultimate load, deflections.
Chain................	Proof tests of entire chain in tension, tests to destruction of sample sections.	Set after removal of proof load, ultimate strength.
Large pipe...........	Hydrostatic pressure proof test.	Observation of leaks, cracks, or other evidence of failure.
Gear teeth...........	Scleroscope or Rockwell test for uniform hardness.	Hardness for various teeth.
Engraver's plates......	Brinell, Rockwell, or scleroscope tests for uniform hardness of samples.	Hardness at various points.
Strain insulators for electric transmission lines.	Proof load in tension, tension test of samples to destruction.	Evidences of failure under proof load, ultimate strength.
Eyebars..............	Tension test of sample eyebars to destruction.	Yield point, ultimate load, stretch.
Columns.............	Compression tests of models or samples to destruction.	Yield point, ultimate load, deflection, axial compression.

should be tested with spherical-seated bearing blocks. Wood has a rather poorly defined proportional limit in compression. In compression along the grain there is a well-defined ultimate strength. Shearing tests along the grain are made by the use of shearing blocks placed in the testing machine, or for larger specimens by testing short, deep beams. The shearing strength of wood along the grain is of great importance. Flexure tests both of small selected specimens and of large beams are common. In flexure tests the failure may be by longitudinal shear along the neutral axis, by compression along the upper side of the beam, or by tension along the lower side. Impact flexure tests show the shock-resisting qualities of wood. Hardness tests are made by using a steel ball 0.444 in. in diameter, and noting the load which causes the ball to penetrate to one-half its diameter.

The Turner-Hatt impact testing machine is in common use in the United States for impact testing of wood. This machine consists of an anvil on which the specimen is placed, and of a weight which can be dropped from various heights. Attached to the weight is a pencil which draws a record on a rotating drum. From this record the deflections of the specimen can be measured, as the weight is dropped from successively increasing heights until rupture occurs, or until the deflections increase abnormally, showing that the proportional limit has been passed. Another method of making an impact test consists in dropping the weight from such a height that the specimen is fractured by one blow. The pencil attached to the weight traces a curve on the rotating drum whose steepness is a measure of the velocity of the falling weight. Measuring the velocity of the weight before and after fracture of the specimen the energy absorbed in fracturing the specimen can be determined. For detailed description of tests of timber, see the *A.S.T.M. Standards* D143–27 and D198–27.

MECHANICS OF FLUIDS

PROPERTIES OF FLUIDS, DIVISIONS OF FLUID MECHANICS

1. INTRODUCTION, DEFINITIONS

Continuous Media. In the study of mechanics of fluids the fluids are usually regarded as *continuous media* and not as an *aggregation of discrete particles.* This conception is in conflict with the molecular theory, but it is sufficiently accurate for most engineering purposes and permits progress to be made, whereas to regard fluids as made up of separate particles presents insuperable difficulties in general.

This means then that volume elements are restricted to those whose dimensions are large in comparison with the mean free paths of the molecules contained within the volume element. In small time-intervals the average number of molecules contained in the element is then sensibly constant. That this conception of a fluid enables the investigator to make a fairly detailed and accurate exploration of a given space filled with fluid is illustrated by the fact that for air at normal temperatures a cube of side 0.001 mm contains 2.7×10^7 molecules.

Exceptions occur in the study of (*a*) *diffusion,* where there is a measurable interchange of molecular matter; (*b*) *heat conduction,* where there is an interchange of molecular kinetic energy; and (*c*) *internal friction,* where there is interchange of momentum between adjacent layers of the fluid.

In order to call attention to those properties of fluids which differentiate them from solids, the terms *bulk modulus* and *rigidity modulus* will be used.

The Bulk Modulus.

$$k = S_n/(\Delta v/v) \tag{1}$$

where S_n = normal force on each unit of area of a small cubical element.
v = original volume of the element.
Δv = change in volume of the element due to stress S_n.

The Rigidity Modulus.

$$N = S_s/\theta \tag{2}$$

where S_s = tangential or shearing force on each unit of area of opposite sides of a small cubical element.
θ = shearing deformation due to the stress S_s.

Fluids and Solids. Fluids have bulk moduli but no rigidity moduli; a solid has both. A fluid therefore cannot permanently resist a tangential or shear stress. The fluid yields to such stresses, different fluids yielding at different rates.

This illustrates that it is very difficult to define sharply the line of demarcation between solids and fluids. For instance, a steel ball placed on the surface of a bucket of pitch will eventually sink to the bottom. The shearing stresses caused by the relatively greater weight of the steel ball cannot be permanently resisted by the pitch. In this sense the pitch acts like a fluid. On the other hand, a tuning fork made of pitch acts like a steel tuning fork when it is struck. In this sense pitch behaves like a solid.

2. PROPERTIES OF FLUIDS

Density

Mass Density, defined as the mass per unit volume, is most frequently used. Symbol: ρ.
Weight Density, defined as the weight per unit volume, is also used. Symbol: w.
Then

$$\rho = w/g \tag{3}$$

where g is the acceleration due to gravity. If the symbol [ ] denotes dimensional equality, then $[\rho] = \left[\frac{M}{L^3}\right]$, M and L denoting the fundamental quantities mass and length respectively. In engineering units, mass density, ρ, is then found in slugs per cubic foot.

Specific Density in relation to water at 4.0° C is often used to specify density of certain fluids.

Density varies widely for different fluids. For a given fluid, density varies chiefly with temperature and pressure. Densities of a number of fluids are given at the end of this section.

Compressibility

Definition. Since this property of a fluid depends upon its bulk modulus, compressibility is defined in terms of the bulk modulus, k. The equation $k = S_n/(\Delta v/v)$ shows that, when the normal stress, S_n, is large for small values of Δv, the fluid is relatively more difficult to compress than it is when large values of Δv correspond to moderate values of S_n. For an incompressible fluid, $k = \infty$.

Compressibility, symbol β, is defined as the reciprocal of the bulk modulus, k. Hence this compressibility number is zero for an incompressible fluid.

For Certain Fluids, compressibility is given as the contraction in unit volume, $\Delta v/v$, per atmosphere because very large values of the normal force S_n are required to obtain measurable values of $\Delta v/v$. For other fluids such as air, hydrogen, etc., pressure changes very much with temperature, and very frequently compressibility is written:

$$\beta = \text{compressibility} = \frac{1\,(\partial v)}{v\,(\partial p)}\,T' = \text{constant} \qquad (4)$$

where
p = pressure in the fluid.
T = absolute temperature.

β is also written:

$$\beta = \frac{1(v_1 - v_2)}{v_1(p_2 - p_1)}\,T = \text{constant} \qquad (5)$$

Compressibilities of a number of fluids are given at the end of this section.

Viscosity

Theory. Suppose that a fluid is in motion over a plane surface, S (Fig. 1). Consider two surfaces in the fluid at distances y and $y + dy$ from this surface, S. Let u and $u + du$ be the velocities in these two surfaces in an X direction. It will be assumed that u and $u + du$ depend only on y. Observations show that:

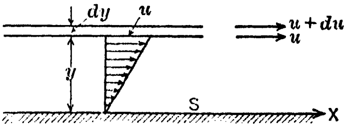

Fig. 1. Fluid Motion Near a Surface

(a) The fluid in contact with S is at rest relative to S.

(b) u is a linear function of y in that part of the fluid where its viscous properties are important.

(c) Tangential stresses exist in the fluid when it is in motion. These tangential stresses retard the more rapidly moving layers of fluid and accelerate the less rapidly moving layers. The tangential stress, S_t, follows Newton's law, i.e.,

$$S_t \propto du/dy \qquad (6)$$

It varies for different fluids or for the same fluid under different conditions.

Consequently,

$$S_t = \mu du/dy \qquad (7)$$

where μ is a constant for a fluid under fixed conditions, i.e., temperature, pressure, etc., of the latter. $[\mu] = \left[\frac{M}{LT}\right]$. In engineering units it will be given in slugs per foot second. The quantity is sometimes called a *coefficient of viscosity*; since it is not a dimensionless number the term is not so apt. Coefficients are usually dimensionless numbers or quantities.

Maxwell Defined Viscosity as: "The tangential force on unit area of either of two horizontal planes of indefinite extent at unit distance apart, one of which is fixed, while the other moves with unit velocity, the space between being filled with the viscous fluid."

Various Units of Viscosity are in use. A *poise* is the value of μ in cgs units, i.e., in grams per centimeter second. The *Saybolt* viscosity of a fluid is the number of seconds of time required for 60 cc of the fluid to flow through a given opening in a standard instrument.

In fluid mechanics the ratio μ/ρ occurs frequently. The symbol used is $[\nu] = \left[\frac{L^2}{T}\right]$, that is, in engineering units it is feet² per second.

Viscosity of Gases usually varies chiefly with temperature and very little with pressure. Viscosity of liquids varies with temperature and pressure. Viscosity tables for a number of fluids are given in Art. 6, p. 6-08.

For Solids the tangential or shear stress is

$$S_t = G\theta \tag{8}$$

where G = shear modulus or rigidity modulus.
θ = shear strain.

For Fluids

$$S_t = \mu \frac{d\theta}{dt} \tag{9}$$

The equation for solids holds within the elastic limits. Beyond that limit a solid acts somewhat like a fluid, for

$$S_t = f\left(\frac{d\theta}{dt}\right) \tag{10}$$

Surface Tension

Surface Tension occurs when there is a " free surface " in the fluid as in water or at interfaces between two fluids, for example, oil and water. Observations show that across any line element drawn in the surface of the fluid there is a tension $\gamma\, ds$, the tension being normal to the element ds and in the tangent plane to the surface at ds. The quantity γ is called the surface tension of the fluid. $[\gamma] = \left[\frac{M}{T^2}\right]$; that is, it is a force per unit length.

For fluids which have comparatively simple molecular structures,

$$\gamma = \gamma_0\,(1\text{-}bt)^n \tag{11}$$

The parameters n and b vary for different fluids. Average values are $n \approx 1.2$ and $b \approx 0.005$, when t = °C. Values of surface tension for a number of fluids are given at the end of this section.

Relations between Properties of Fluids

The properties of fluids mentioned above are not independent of one another. Some relations are known which connect certain of the properties of fluids.

(*a*) If λ is surface energy per unit area, we know from thermodynamics that $\lambda = \gamma - T\frac{\partial\gamma}{\partial T}$.

(*b*) If $\beta = 1/k$ then $\gamma\,\beta^{4/3}$ = constant (Richard & Matthews; *Zeit. phys. Chem.*, 61, 49 (1908)), holds for certain fluids.

(*c*) If M is the molecular weight of the fluid, T_c the critical temperature (absolute), δ and A are constants then $\gamma\frac{(M)^{2/3}}{(\rho)} = A(T_c - T - \delta)$ (Eötvos).

$\delta \approx 6$ and $A \approx 2.12$ for unassociated liquids; symbol $\approx$ denotes approximate equality.

(*d*) $\gamma\frac{(M)^{2/3}}{(\rho)}$ = constant for unassociated liquids, over wide ranges of temperature (Bernett and Mitchell; *Zeit. phys. Chem.*, 84, 475 (1913)).

3. KINDS OF FLUIDS

Ideal Fluids are fluids in which no tangential stresses exist irrespective of whether the fluid is in motion or not.

In spite of the fact that no such fluids actually exist many important advances have been made by considering fluids to be ideal. So-called classical hydrodynamics is largely concerned with ideal fluids.

Liquids are fluids which are practically incompressible. They have definite free surfaces. Density, viscosity, and surface tension are important properties of liquids. Water, alcohol, oil, acetone, etc., are examples of liquids. An ideal liquid is incompressible and inviscid.

Gases are fluids which have no free surfaces. They fill completely any containing vessel. Density and viscosity of gases are generally smaller than for liquids. The compressibility numbers are larger for gases than for liquids; i.e., comparatively small pressures produce large volume changes. For many cases of fluid motion a gas may be considered incompressible.

When gases must be regarded as compressible the temperature affects the pressure and volume very much. It is necessary therefore to know the relation between pressure, volume, and temperature.

A Perfect Gas or ideal gas follows Charles' Law, and the relation between pressure, volume, and temperature is,

$$pv = R'T \tag{12}$$

where p = pressure.
v = volume.
T = absolute temperature.
R' = constant depending on the weight and nature of the gas used.

The equation is also written

$$pv = wRT \tag{13}$$

where w = weight density of the gas.
R = a constant depending only on the nature of the gas.

Since ideal gases do not exist, this equation is not exactly correct for real gases.

Many equations have been proposed to represent the pressure, volume, and temperature relation. Books on thermodynamics should be consulted for discussions on such equations.

4. DIVISION OF FLUID MECHANICS

Fluid Statics is concerned with fluids at rest or in equilibrium. There is no motion in any part of the fluid provided it is regarded as a continuous medium.

Hydrostatics, aerostatics, referring to water and air respectively as fluids, are terms in common use.

Pressure and buoyancy are examples of statical fluid forces.

Fluid Dynamics is concerned with forces arising from the motion of fluids.

Separate subdivisions of fluid dynamics are:

(*a*) Hydrodynamics referring to water as the fluid in motion.

(*b*) Aerodynamics referring to air as the fluid in motion.

(*c*) Gas dynamics referring to gases and vapors as the fluids in motion.

Hydraulics is a term which refers to engineering applications of fluid mechanics, both fluid statics and fluid dynamics. Most generally water is the fluid considered in hydraulics.

5. DENSITY OF VARIOUS LIQUIDS AND GASES

All numerical values were taken from the International Critical Tables with the exception of the standard atmosphere relations used in aeronautical work, which were taken from Technical Report 218 (1925), National Advisory Committee for Aeronautics.

Symbols:

$d_{t_1}{}^t$ = weight in grams per millimeter = specific gravity in terms of water at 4° C; t refers to the temperature, in degrees Centigrade, at which the weight was determined.
w^t = weight in pounds per cubic foot at temperature t.
ρ^t = mass in slugs per cubic foot at temperature t.

Conversion Factors:

1 gram per milliliter = 0.999973 gram per cubic centimeter.
1 pound per cubic foot = 0.016018 gram per cubic centimeter.
1 slug per cubic foot = 0.5154 gram per cubic centimeter.

Table I. Density of Water from 0° C to 100° C

t° C	$d_4{}^t$	$\rho = w/g$ = mass density *	t° C	$d_4{}^t$	$\rho = w/g$ = mass density *

Table IV. Density of Ethyl and Methyl Alcohol at Various Temperatures

This shows how density varies with temperature for these two liquids. The equations are empirical, and the liquids are assumed to be chemically pure.

Methyl alcohol: (a) $d_4^t = 0.80999 - 9.253 \times 10^{-4}t - 4.1 \times 10^{-7}t^2$
Range: $t = 0°$ C to $t = 60°$ C

(b) $d_4^t = 0.81015 - 1.0041 \times 10^{-3}t - 1.802 \times 10^{-6}t^2$
Range: $t = -94.5°$ C to $t = 0°$ C

Ethyl alcohol: (a) $d_4^t = 0.80625 - 8.461 \times 10^{-4}t + 1.60 \times 10^{-7}t^2 - 8.5 \times 10^{-9}t^3$
Range: $t = 0°$ C to $t = 80°$ C

(b) $d_4^t = 0.80625 - 8.45 \times 10^{-4}t + 2.9 \times 10^{-7}t^2$
Range: Below $t = 0°$ C

No lower temperature specified (Timmermans).

Table V. Density of Air (Aeronautics)

Standard density $= \rho_0 = 2.378 \times 10^{-3}$ slug per cu ft at $t = 15°$ C, $p_0 = 760$ mm Hg, dry air
Variation of density with pressure and temperature:

$$\rho/\rho_0 = 0.3789 \frac{p \text{ mm Hg}}{(t° \text{ C} + 273° \text{ C})}$$

$$= 9.624 \frac{p \text{ in. Hg}}{(t° \text{ C} + 273° \text{ C})}$$

$$= 17.32 \frac{p \text{ in. Hg}}{(t° \text{ F} + 459.4°)}$$

Variation of density with altitude:

$$\rho/\rho_0 = \left[1 - \frac{3.566 \times 10^{-3}}{(t° \text{ F} + 459.4° \text{ F})} h\right]^{4.256} ; \; h = \text{altitude in feet}$$

Table VI. Density of Various Gases

Density given at 0° C and 760 mm Hg. Symbol for density = *ds*

Gas	$ds \times 10^3$ (gm/ml)	w (lb/ft^3)	ρ (slugs/ft^3)
Acetylene	1.173	0.0732	0.00227
Ammonia	0.7710	.0481	.00150
Carbon dioxide	1.977	.1234	.00383
Carbon monoxide	1.250	.0780	.00242
Helium	0.1785	.0112	.000346
Hydrogen	0.08988	.00561	.0000174
Hydrogen chloride	1.639	.1023	.00318

Table X. Viscosity of Gases—Sensibly Independent of Pressure

$\mu = \mu_0 \left(\frac{T_0 + C}{T + C}\right)\left(\frac{T}{T_0}\right)^{3/2}$; μ in poises, T in deg K. C is called Sutherland's constant.

Gas	Value of C	μ_0 at $t°$ $\times 10^6$	$t°$ C	Gas	Value of C	μ_0 at $t°$ $\times 10^6$	$t°$ C
Air	120	170.9	0	Hydrogen (average)	77.5	84.2	0
Ammonia	370	91.8	0	Krypton	188	232.7	0
Carbon dioxide	240	137.0	0	Neon	56	297.3	0
Carbon monoxide	118	166.0	0	Nitrogen	111	176.5	23°
Helium	70	187.3	0	Oxygen	127	203.9	23°

Viscosity of Oils is often given in time of efflux through certain types of viscometers.

Kinematic Viscosity $\nu = \frac{\mu}{\rho}$ may be obtained from the time of efflux through various types of commercial viscosmeters by means of the equations:

$$\text{Saybolt Universal:}\quad \frac{\mu}{\rho} = 2.20 \times 10^{-3}\,t - \frac{1.80}{t}$$

$$\text{Redwood:}\quad \frac{\mu}{\rho} = 2.60 \times 10^{-3}\,t - \frac{1.715}{t}$$

$$\text{Engler:}\quad \frac{\mu}{\rho} = 1.47 \times 10^{-3}\,t - \frac{3.74}{t}$$

$$\text{Redwood Admiralty:}\quad \frac{\mu}{\rho} = 2.70 \times 10^{-3}\,t - \frac{20}{t}$$

where

μ = absolute viscosity in poises
ρ = density in grams per cu cm
t = time of efflux in seconds

} At room temperature.

To reduce to units of ft² per sec multiply the above by 1.076×10^{-3}.

7. SURFACE TENSION; CAPILLARY RISE

All numerical values were taken from the International Critical Tables. Surface tension γ is given in dynes per centimeter or pounds per foot. Capillary rise is given by

$$a^2 = hr = \frac{2\gamma}{(w_L - w_G)g}$$

where

h = height of capillary rise.
r = internal radius of capillary tube.
γ = surface tension.
w_L = weight density of liquid.
w_G = weight density of gas or vapor above liquid.

This formula holds strictly for cases where the angle of contact between liquid and glass is 0° and the meniscus may be considered hemispherical in shape. The angle of contact is 0° for many liquids. Examples: Water, ethyl alcohol, benzene, carbon tetrachloride, chloroform, acetic acid, aqueous solutions of various salts, glycerol, ethyl ether, turpentine, olive oil, and hydrogen peroxide.

Conversion Factor: γ (dyne/per centimeter) $\times 6.86 \times 10^{-5} = \gamma$ (poundals per foot).

−50°	$pv = 0.81655 + 5.32 \times 10^{-4} p + 9.4 \times 10^{-8} p^2$
0°	$pv = 0.99945 + 5.29 \times 10^{-4} p$
50°	$pv = 1.18245 + 5.24 \times 10^{-4} p$

OXYGEN

Range: 0 to 100 atmospheres

t° C	pv
0°	$pv = 1.001 - 9.94 \times 10^{-4} p + 2.19 \times 10^{-6} p^2$
20°	$pv = 1.07425 - 7.52 \times 10^{-4} p + 1.50 \times 10^{-6} p^2$
100°	$pv = 1.3674 - 1.60 \times 10^{-4} p + 1.37 \times 10^{-6} p^2$

The average compressibility modulus in an interval may be calculated from

$$\beta = -\frac{p_2 - p_1}{\dfrac{K_2 p_1}{K_1 p_2} - 1}$$

for a constant temperature.

FLUID STATICS

9. FLUID PRESSURE

It is a fact of common experience that, if a solid body be surrounded by a fluid, the surface areas of the solid body experience forces due to the presence of the fluid. If the fluid is in equilibrium the surface force on the solid body is perpendicular to the surface on which it acts and its direction is always from fluid to body. Since no tangential stresses exist in a fluid at rest there can be no component other than the normal component. This surface force per unit of area is called pressure. In engineering units it is most frequently convenient to express pressure in pounds per square foot.

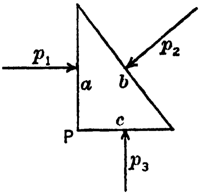

FIG. 1. Fluid Pressures on a Triangular Prism

Consider a triangular prism (Fig. 1) whose end faces are triangles of sides a, b, and c; the length of the prism may be unity. To be in equilibrium the vector sum of the forces, $p_1 a$, $p_2 b$, $p_3 c$, due to the pressures on the faces of the prism, is zero and $p_1 = p_2 = p_3$. This does not depend on the size of the prism and if the prism shrinks in size so that b remains parallel to its original direction, the values of p_1, p_2, and p_3 remain equal. Therefore, *in a fluid in equilibrium the pressure at a point* P *is independent of the orientation of the surface element on which it acts.*

This statement is true for viscous as well as inviscid fluids, provided they are in equilibrium.

10. RELATION BETWEEN PRESSURE AND BODY FORCES

By body forces are meant forces like gravitational forces. Consider a small fluid cylinder (Fig. 2) of weight density w immersed in a fluid having the same weight density. Let the height of the cylinder be dh and its cross-sectional area dA. If the axis is vertical then we have for equilibrium, if p and $p + dp$ are the pressures on the top and bottom faces,

$$w = \rho dh dA \cdot g = (p + dp - p)dA = dp dA \quad \text{or} \quad \frac{dp}{dh} = \rho g \qquad (1)$$

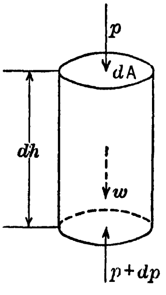

FIG. 2. Static Fluid Forces on an Element of Fluid

11. APPLICATIONS OF EQUATION $\frac{dp}{dh} = \rho g$

Aerostatics

Temperature and Pressure, Variation with Altitude. This equation is used in aerostatics. Choose h positive when directed from the earth's surface upward. Then since pressure in the atmosphere diminishes as h increases,

$$-\frac{dp}{dh} = \rho g$$

Then
$$h - h_1 = \frac{1}{g}\int_p^{p_1} \frac{dp}{\rho} \qquad (2)$$

where p corresponds to height h and p_1 to height h_1. Strictly g is not constant as h changes.

Actually $g \approx g_0 \left(\frac{1}{1 + \frac{h}{R_0}} \right)^2$ where g_0 = acceleration of gravity and R_0 = radius of the earth. Since $\frac{h}{R_0}$ is usually small, $g \approx g_0 \left(1 - \frac{2h}{R_0}\right)$, then more accurately,

$$h - h_1 + \frac{h_1^2 - h^2}{R_0} = \frac{1}{g_0}\int_p^{p_1} \frac{dp}{\rho} \qquad (3)$$

This introduces small errors and (2) is generally used. Using the ideal gas law $pv' = RT$, where $v' = \frac{v}{w} = \frac{1}{w}$ = specific volume in cubic feet per pound.

Hence $\frac{1}{\rho} = vg$ and we have,

$$h - h_1 = R\int_p^{p_1} T\frac{dp}{p} \tag{4}$$

If the "polytropic law" $Pv^n =$ constant holds, then from (2) and the gas law,

$$h - h_1 = \frac{n}{n-1}R\,(T_1 - T) \tag{5}$$

In a Polytropic Atmosphere the temperature is a linear function of the height. Also,

$$p = p_1\left(1 - \frac{(n-1)}{nRT_1}(h - h_1)\right)^{n/(n-1)} \tag{6}$$

which shows how the pressure varies with altitude.

Assume an Isothermal Atmosphere, then

$$T = T_0 = \text{constant}$$

and

$$h - h_1 = RT_0 \log_e \frac{p_1}{p} \tag{7}$$

Since barometer reading, b, is proportional to pressure,

$$h - h_1 = RT_0 \log_e \frac{b_1}{b} \tag{8}$$

Atmospheric Regions. Actually the atmosphere is separated into two regions. The lower part called the *troposphere* is about 35,000 feet high at our latitude. In the troposphere $n \approx 1.2$, which corresponds to a semihumid adiabatic atmosphere. Above the troposphere is the *stratosphere,* where the temperature is practically constant at −67° F and $n = 1$.

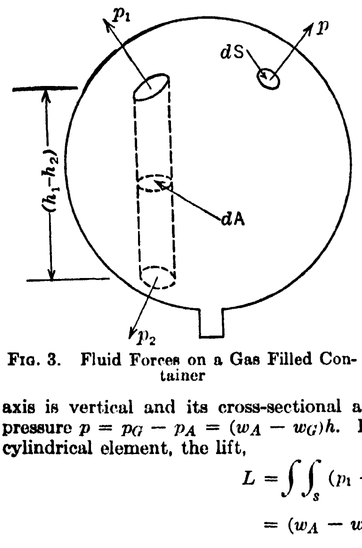

FIG. 3. Fluid Forces on a Gas Filled Container

Lift of Gas-filled Aircraft. Let $w_A =$ average weight density of the air in the vicinity of the balloon or aircraft.

$w_{c_1} =$ weight density of the air in the gas containers.

From the equation $\frac{dp}{dh} = -\rho g = -w$,

$p_A = p_o - w_A h$, $p_o =$ pressure at $h = 0$ and $P_A =$ pressure of air on the outside of the gas container.

$p_G = p_o - w_g h$, $p_G =$ pressure of gas on the inside of the gas container. Take a cylindrical element of the gas container (Fig. 3); the axis is vertical and its cross-sectional area is dA. At any point of the surface the net pressure $p = p_G - p_A = (w_A - w_G)h$. If p_1 and p_2 are net pressures at the ends of the cylindrical element, the lift,

$$\begin{aligned} L &= \int\!\!\int_s (p_1 - p_2)dA \\ &= (w_A - w_G)\int\!\!\int\!\!\int_v (h_1 - h_2)dA \\ &= (w_A - w_G)V = (W_A - W_G) \end{aligned} \tag{9}$$

$v =$ volume of the gas container; W_A and W_G are the weights of air displaced and the weight of the gas.

If the gas container is filled with non-homogeneous gas,

$$p = p_A h - \int_0^h w_G dh$$

Then $L = \int\!\!\int_s pds = w_A v - \int\!\!\int\!\!\int_v w_G dv = W_A - W_G$ as before.

Effect of Temperature on Lift.

Using the gas law, $p = wRT$,

$$L = pv\left(\frac{1}{R_A T_A} - \frac{1}{R_G T_G}\right),\ p = w_A R_A T_A = w_G R_G T_G$$

$$L = w_A v\left(1 - \frac{R_A T_A}{R_G T_G}\right) = W_A\left(1 - \frac{R_A T_A}{R_G T_G}\right) \tag{10}$$

Hydrostatics

Hydraulics. If the fluid is water, then p and w are constant

and
$$h - h_1 = \frac{1}{w}(p - p_1)$$

or
$$p = p_1 + w(h - h_1)$$

h is here regarded as positive when directed downward. There is no loss in generality in choosing $h_1 = 0$, so p_1 = atmospheric pressure and

$$p = p_1 + wh \tag{11}$$

Suppose an irregular plane area A (Fig. 4) is submerged vertically in a liquid of weight density w. The total pressure on an element dA, parallel to the free surface, is

$$p = \iint_A (p - p_1)\,dA = w\iint_A h\,dA = w\bar{h}A \tag{12}$$

h = distance of element dA from free surface.
$\bar{h}$ = distance of centroid of A from free surface.

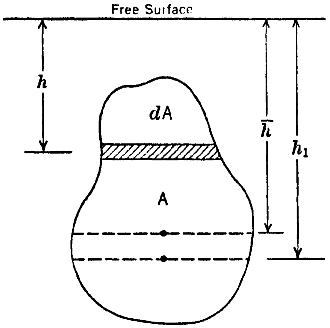

FIG. 4. Fluid Pressure on a Vertically Submerged Surface

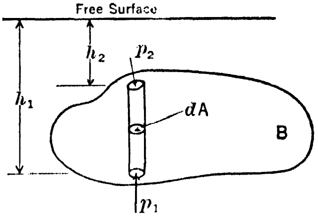

FIG. 5. Buoyant Forces on an Immersed Body

To find where the pressure acts,

$$ph_1 = \iint_A (p - p_1)\,h\,dA = w\iint_A h^2 dA = wI.$$

h_1 = distance of center of pressure below free surface.
I = moment of inertia of A about an axis in the free surface and plane of A.
$I = A\bar{h}^2 + \bar{I}$, $\bar{I}$ = moment of inertia of A about an axis through the centroid of A parallel to the axis in the free surface.

Then, $p\bar{h} + pa = wA\bar{h}^2 + w\bar{I} = p\bar{h} + w\bar{I}$

where
$$a = \frac{\bar{I}}{A\bar{h}}, \quad h_1 = \bar{h} + \frac{\bar{I}}{A\bar{h}} \tag{13}$$

Archimedes' Law. Consider a solid body, B (Fig. 5), submerged in a liquid. Divide the body into small cylindrical elements of cross-section dA and having their axis vertical. Let the ends of the cylinders be at distances h_1 and h_2 from the free surface of the liquid. The lift, L, experienced by the body, is

$$L = \iint_A (p_1 - p_2)\,dA = \iiint_B w(h_1 - h_2)\,dA = wv$$

r = volume of the body. (14)
w = weight density of the fluid.

This is *Archimedes' Law*: A body completely immersed in a fluid experiences a lift equal in magnitude to the weight of fluid displaced. This lift acts at the center of gravity of the displaced liquid.

Stability of a Completely Immersed Body:

(*a*) Stable if center of gravity of body is vertically below the center of gravity of displaced fluid.

(*b*) Unstable if the two centers of gravity are reversed as to position.

(*c*) Neutral if the two centers of gravity coincide as to position.

12. SURFACE TENSION AND PRESSURE

Theory. Consider a curved free surface of a liquid (Fig. 6). Suppose that the surface is a cylinder whose generators are perpendicular to the plane of the paper and that the height is unity. The forces acting on a small element $AB \times 1 = ds \times 1$ are shown. Resolving normal to the surface, and letting θ become small, $\gamma\theta = \Delta p ds$. If R is radius of curvature at A,

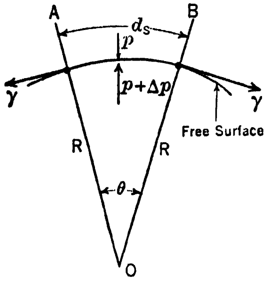

FIG. 6. Surface Tension on an Element

$$\Delta p = \frac{\gamma}{R} \qquad (15)$$

Δp = pressure increment due to surface tension. When R becomes small this increase in pressure becomes appreciable. The excess of pressure due to surface tension is directed from the concave towards the convex side.

If the Surface has Double Curvature,

$$\Delta p = \gamma\left(\frac{1}{R_1} + \frac{1}{R_2}\right) \qquad (16)$$

R_1 and R_2 are principal radii of curvature at the point where Δp is measured.

For a Spherical Drop or a spherical air bubble in a liquid,

$$\Delta p = \frac{\gamma}{d} \qquad (17)$$

d = diameter of the drop or bubble.

For a Spherical Soap Bubble, which has two surfaces,

$$\Delta p = \frac{2\gamma}{d} \qquad (18)$$

Rise in a Capillary Tube and Surface Tension. Observation shows that liquids meet solids at definite angles of contact. Water, for instance, meets glass at a zero angle of contact. Inside a capillary tube (Fig. 7), the surface is sharply curved and the pressure increment due to the surface tension will cause the surface in the tube to rise to a height, h. The pressure due to the head h must balance the pressure increment due to surface tension and the pressure at P is then atmospheric.

Then $\frac{2\gamma}{r} = wh$ (19) if it is assumed that the surface AB is hemispherical.

$$w = w_L - w_G$$

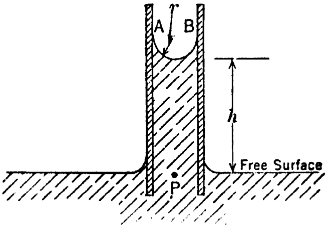

FIG. 7. Rise in Capillary Tube Due to Surface Tension.

where w_L = weight density of the liquid and w_G = weight density of the gas above the liquid.

FLUID DYNAMICS

13. LAWS OF FLUID MOTION

Mathematical Statement. The general differential equations of fluid motion are known as the Navier-Stokes Equations.

$$\frac{\partial u}{\partial t} + u\frac{\partial u}{\partial x} + v\frac{\partial u}{\partial y} + w\frac{\partial u}{\partial z} = X - \frac{1}{\rho}\frac{\partial p}{\partial x} + \frac{\mu}{\rho}\left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2}\right)$$

$$\frac{\partial v}{\partial t} + u\frac{\partial v}{\partial x} + v\frac{\partial v}{\partial y} + w\frac{\partial v}{\partial z} = Y - \frac{1}{\rho}\frac{\partial p}{\partial y} + \frac{\mu}{\rho}\left(\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} + \frac{\partial^2 v}{\partial z^2}\right)$$

$$\frac{\partial w}{\partial t} + u\frac{\partial w}{\partial x} + v\frac{\partial w}{\partial y} + w\frac{\partial w}{\partial z} = Z - \frac{1}{\rho}\frac{\partial p}{\partial z} + \frac{\mu}{\rho}\left(\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2} + \frac{\partial^2 w}{\partial z^2}\right)$$

u, v, w, are velocity components in x, y, and z directions of Cartesian coordinates, and X, Y, and Z are body forces per unit of volume in direction of coordinate axes, t is time, p is pressure per unit of area, ρ is mass density, and μ is the coefficient of viscosity.

No General Solutions of these equations have been found. There is therefore no general theoretical treatment of fluid motion. Special solutions are known for certain kinds of motion. Some of these will be indicated in the following sections.

Similarity Laws, Dimensional Analysis

In view of the difficulty of solving the general differential equations of fluid motion other methods are employed. One of the most helpful methods is that of applying dimensional analysis to obtain criteria for dynamically similar motions of fluids.

Dynamical Similarity. If the flows of two fluids around geometrically similar bodies are also geometrically similar then the two flows are dynamically similar if the corresponding fluid forces on the two bodies are proportional at any instant.

Inertia and Viscous Forces. In many important cases inertia and viscous forces are the only ones to be taken into account.

$$\frac{\text{Inertia force}}{\text{Viscous force}} = \frac{\rho VL}{\mu} = \frac{VL}{\nu} \qquad (2)$$

L is a typical dimension of the body, V is velocity of the flow, ρ, μ and ν have been defined. This number is called *Reynolds' number*, $\left[\frac{\rho VL}{\mu}\right] = [M^0L^0T^0]$; i.e., it is a dimensionless number. This means that its value is the same no matter what system of consistent units is used. When $\frac{\rho_1 V_1 L_1}{\mu_1} = \frac{\rho_2 V_2 L_2}{\mu_2}$ in two flows they are dynamically similar.

When Reynolds' number is large, inertia forces predominate in comparison with viscous forces. When it is small the reverse is true. Most problems in aerodynamics are concerned primarily with viscous and inertia forces.

Inertia and Gravity Forces Predominate.

$$\frac{\text{Inertia force}}{\text{Gravity force}} = \frac{V^2}{Lg} \qquad (3)$$

L is a typical dimension, g is the acceleration of gravity, and V is the velocity of the flow.

$$\left[\frac{V^2}{Lg}\right] = [M^0L^0T^0]$$

it is also dimensionless and has the same value in any consistent set of units. This number is called *Froude's number*. When $\frac{V_1^2}{L_1 g} = \frac{V_2^2}{L_2 g}$ the motions are dynamically similar. This criterion of similarity occurs for motions of partly submerged bodies like surface ships and seaplanes.

Inertia Force and Compressibility Predominate.

$$\frac{\text{Inertia force}}{\text{Pressure force}} = \left(\frac{V}{V_c}\right)^2$$

V_c is the velocity of sound in the fluid at a given temperature, V is the velocity of the flow. $\left[\frac{V}{V_c}\right] = [M^0L^0T^0]$; it is dimensionless and has the same value in any consistent set of units. This number is called *Mach's number*.

This criterion of similarity is of importance in fluid motion where the velocity is comparable with the speed of sound in the given fluid.

Surface Tension and Inertia Predominate.

$$\frac{\text{Surface tension force}}{\text{Inertia force}} = \frac{\gamma}{\rho V^2 L} \tag{4}$$

where γ = surface tension in units of force per unit of length. $\frac{\gamma}{\rho V^2 L^2}$ is also dimensionless and has the same value in any consistent set of units. It is called *Weber's number*. This criterion is of importance in motions where the surface tension effects become appreciable.

It is not possible in general, in a practical sense, to satisfy the condition of similarity in flows where three or more of the types of forces mentioned occur. For example, we find that it is impossible to satisfy Reynolds' law and Froude's law simultaneously unless we use different fluids. The two fluids must be so chosen that

$$\frac{\nu_1}{\nu_2} = \left(\frac{V_1}{V_2}\right)^3 = \left(\frac{L_1}{L_2}\right)^{3/2}$$

Practically two fluids of sufficiently different ν and other suitable characteristics do not exist.

Dimensional Analysis. This method is mathematical but fairly simple. It is assumed that the fluid force is dependent on certain variables or quantities and the expression for the fluid force can then be found in terms of these assumed quantities by expressing each quantity in terms of certain fundamental quantities such as: mass, M; length, L; time, T. The expression for force obtained contains unknown functional combinations of one or more dimensionless combinations of the quantities upon which the force has been assumed to depend.

Example: Suppose the fluid force, F, depends on the mass (inertia), viscosity, velocity of flow, and upon the size of the body on which F acts. Since a comparison of geometrically similar bodies is to be made, a single quantity will determine the size.

Hence: $F = \phi(\rho, V, \mu, D) = \Sigma \rho^a V^b \mu^c D^e$

where F = fluid force.
ρ = mass density of fluid.
V = velocity of flow.
μ = coefficient of viscosity.
D = typical dimension of the body on which F acts.
ϕ = function symbol.

Now $[F] = \left[\frac{ML}{T^2}\right]$; $[\rho] = \left[\frac{M}{L^3}\right]$; $[V] = \left[\frac{L}{T}\right]$; $[\mu] = \left[\frac{M}{LT}\right]$; $[D] = [L]$.

Then $[F] = \left[\sum \left(\frac{M}{L^3}\right)^a \left(\frac{L}{T}\right)^b \left(\frac{M}{LT}\right)^c L^e\right] = \left[\frac{ML}{T^2}\right]$

Each term of the summation must have the same dimensions in the fundamental quantities M, L, and T.

This leads to the equations:

$$\begin{aligned} a + c &= 1 \\ -3a + b - c + e &= 1 \\ b + c &= 2 \end{aligned}$$

We can solve for three of the quantities in terms of the fourth. The choice is immaterial. For instance,

$$a = 1 - c;\ b = 2 - c;\ e = 2 - c$$

Hence
$$\begin{aligned} F &= \Sigma \rho^{(1-c)} V^{(2-c)} \mu^c D^{(2-c)} \\ &= \rho V^2 D^2 \sum \left(\frac{\rho V D}{\mu}\right)^{-c} \\ &= \rho V^2 D^2 \psi\left(\frac{\rho V D}{\mu}\right) \end{aligned}$$

Then
$$\frac{F}{\rho V^2 D^2} = C_F = \psi\left(\frac{\rho V D}{\mu}\right)$$

where C_F is a dimensionless number called the force coefficient. This coefficient varies for geometrically similar bodies tested at different speeds and in different fluids, but it varies according to a fixed law expressed by the function symbol. That is, if many separate measurements of F were made by varying body size (but not shape), fluid, and fluid velocity a single curve $C_F \propto \rho\frac{VD}{\mu}$ would be found like the one shown in Fig. 1.

The form of this curve or the form of the ψ function cannot be determined by analysis except in special cases. Experiments must be made to determine the curve. If the choice of the variables upon which F depends has been correctly made the experimentally determined points fall on a single curve. If the results do not fall on a single curve there has been an important omission in the choice of quantities upon which F was assumed to depend. Once a single curve is obtained, however, the result may be used with confidence. In this case the force would represent the fluid force on a body completely immersed in the fluid, and within fairly wide ranges C_F, the force coefficient, would apply to various fluids, speeds, and body size. Shapes would always have to remain geometrically similar.

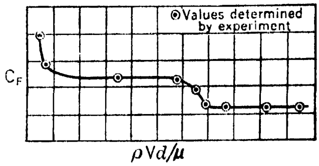

FIG. 1. Typical Variation of Force Coefficient C_F

If the equations had been solved in the form:

$$a = b - 1;\ c = 2 - b;\ e = b$$

the expression for F would have been

$$F = \frac{\mu^2}{\rho}\psi'\left(\frac{\rho VD}{\mu}\right) \quad \text{and} \quad C_F = \psi'\left(\frac{\rho VD}{\mu}\right) = \frac{F}{\frac{\mu^2}{\rho}}$$

A different curve obtained by plotting C'_F against $\frac{\rho VD}{\mu}$ would now be obtained.

Since forces are to be proportional for dynamically similar motions the criterion obtained from the expression for F becomes

$$\frac{\rho_1 V_1 D_1}{\mu_1} = \frac{\rho_2 V_2 D_2}{\mu_2}$$

for flows around geometrically similar bodies.

Example: Suppose that the force F depends in addition to the quantities of the previous example upon the acceleration of gravity g; $[g] = \left[\frac{L}{T^2}\right]$.

Then $$F = \Sigma \rho^a V^b \mu^c D^e g^f$$

$$a = 1 - c;\ b = 2 - c - 2f;\ e = 2 - c + f$$

and $$F = \rho v^2 D^2 f\left(\frac{\rho VD}{\mu}, \frac{V^2}{Dg}\right)$$

The criteria for similarity of two flows about geometrically similar bodies are:

$$\frac{\rho_1 V_1 D_1}{\mu_1} = \frac{\rho_2 V_2 D_2}{\mu_2} \quad \text{and} \quad \frac{V_1^2}{D_1 g_1} = \frac{V_2^2}{D_2 g_2}$$

$C_F = \frac{F}{\rho V^2 D^2} = f\left(\frac{\rho VD}{\mu}, \frac{V^2}{Dg}\right)$ would now be plotted as a surface with $\frac{\rho VD}{\mu}$, $\frac{V^2}{Dg}$, and C_F plotted along three axes.

Scale Effect. If the expression for force is $F = C_F \rho V^2 D^2$ we may compute the force, F, from model tests by using

$$F = \frac{C_F}{C_{F_m}} F_m \left(\frac{\rho}{\rho_m}\right)\left(\frac{V}{V_m}\right)^2\left(\frac{D}{D_m}\right)^2$$

The subscript m refers to values obtained in the model tests. If there is no scale effect the motions are dynamically similar and $C_F = C_{F_m}$.

General Rule for Determining Dynamical Similarity by Dimensional Analysis. Let Q = quantity to be studied. Q may be a force, volume, or mass discharged in a given time, etc. Let $q_1, q_2 \ldots q_n$ be the variables upon which Q is assumed to depend.

Rule: Form an expression in $q_1, q_2 \ldots q_n$ which has the dimensions of Q in M, L, and T (or any other convenient set of fundamental quantities). Divide Q by this expression to form the quantity coefficient, C_Q. Next form all the *dimensionless combinations* of some or all of the quantities $q_1, q_2, \ldots q_n$ which can be made. There are always $(n - m)$ of these dimensionless combinations, m denotes the number of fundamental quantities, i.e., if M, L, and T are used $m = 3$. Call these dimensionless combinations: $K_1, K_2 \ldots K_{n-m}$.

Then $$C_Q = \phi(K_1, K_2 \ldots K_{n-m}) \tag{5}$$

where ϕ is a functional symbol and the nature of the function must be determined by experiment. For dynamically similar motions $K'_1 = K''_1$, $K'_2 = K''_2, \ldots. K'_{n-m} =$

K''_{n-m}, the primes representing values of the K's for flows around geometrically similar bodies.

Example: Let us find the expression for the volume of flow per second, Q, through a thin orifice of radius r, the pressure causing the flow being p. Let the fluid be viscous and incompressible. The variables on which Q depends are: p, ρ, r, and μ.

(*a*) a, b, c, d must be determined so that

$$[\rho^a p^b r^c \mu^d] = \left[\frac{L^3}{T}\right]$$

Using M, L, and T as the fundamental quantities $a = b - 1$, $c = 2b - 2$, $d = 1 - 2b$, then $\rho^a p^b r^c \mu^d = \rho^{b-1} p^b r^{2b-2} \mu^{1-2b} = Q_o$. For any value of b this expression has the dimension of Q. When $b = 1/2$, $Q_o = r^2\sqrt{\frac{p}{\rho}}$. Then

$$C_Q = \frac{Q}{r^2\sqrt{\frac{p}{\rho}}}$$

(*b*) Since $n = 4$ and $m = 3$ there is one dimensionless combination, K of the quantities ρ, p, r, and μ. This is readily found as $\frac{r\sqrt{\rho p}}{\mu}$. Hence

$$C_Q = \frac{Q}{r^2\sqrt{\frac{p}{\rho}}} = \psi\left(\frac{r\sqrt{\rho p}}{\mu}\right)$$

The criterion of similarity for flows through thin orifices made in the same manner (i.e., geometrically similar orifices) is $\frac{r\sqrt{\rho p}}{\mu} =$ constant.

14. DYNAMICS OF IDEAL FLUIDS

Although Ideal, i.e., Non-viscous, Incompressible Fluids do not exist in nature, many motions of real fluids resemble ideal fluid motions, wholly or partially, so closely that much may be learned by studying ideal fluid flows. This has been found to hold more and more in recent times when considerably more attention has been devoted to surface and shape refinements than formerly. It has been true especially in aeronautics.

This part of the subject has been known as classical hydrodynamics. Much material exists on this phase of the subject. Only a few of the more important parts will be mentioned.

Two-dimensional Flow of Ideal Fluids

This is usually restricted to steady flow, i.e., a flow in which the stream lines or particle paths do not change with time. Two-dimensional flow or motion is in a system of parallel planes the velocity having the same magnitude and direction at all points of a perpendicular to the set of planes.

Take a set of rectangular axes (Fig. 2), OX, OY, and draw a line (continuous) from O to a point P. Consider a lamina one unit thick perpendicular to this plane as the region in which the flow is studied. The line OP is then the trace of a cylindrical surface whose generators are perpendicular to the XY plane. The volume of flow per unit time, called the flux, across the surface OP is $\int_0^P v_n ds$, where $v_n =$ flow velocity component perpendicular to OP at any point in the element ds of OP. In treatises on theoretical dynamics of fluid mechanics the following is proved.

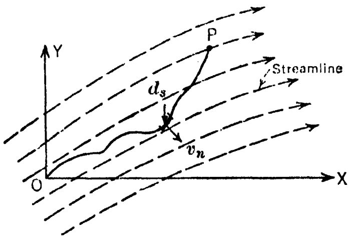

FIG. 2. Steady Flow of Ideal Fluid in Two Dimensions

(a) $\psi = \int_0^P v_n ds$ depends only on the *location* of P and not on the *shape* of the surface OP.

(b) $\psi =$ constant along a stream line. ψ is therefore called the ***stream function.*** **The shape of stream lines for flows of ideal fluids may then be found mathematically.**

(c) $u = \dfrac{\partial\psi}{\partial y}$, $v = -\dfrac{\partial\psi}{\partial x}$, where u, v are x, y components of the velocity vector.

$$\text{Magnitude of velocity vector} = |q| = \sqrt{u^2 + v^2} = \sqrt{\left(\frac{\partial\psi}{\partial y}\right)^2 + \left(\frac{\partial\psi}{\partial x}\right)^2}$$

$$\text{Slope of velocity vector} = \frac{v}{u} = -\frac{\partial\psi/\partial x}{\partial\psi/\partial y}$$

Points at which $q = 0$ are called stagnation points of the flow.

(d) $\phi = \int_0^P v_s ds$ is called the *velocity potential* of the flow where v_s is the flow velocity component parallel to OP at any point on the element ds.

(e) $u = \dfrac{\partial\phi}{\partial x}$, $v = \dfrac{\partial\phi}{\partial y}$, $|q| = \sqrt{\left(\dfrac{\partial\phi}{\partial x}\right)^2 + \left(\dfrac{\partial\phi}{\partial x}\right)^2}$, $\dfrac{v}{u} = \dfrac{\partial\phi/\partial y}{\partial\phi/\partial x}$

$$\text{Circulation} = \oint v_s ds \text{ (Fig. 3)}$$

Circulation around a circuit enclosing fluid only is zero.

Circulation around a body B (once completely around the body) has a constant value Γ. Circulation around a small element is $2\omega\, dA$, where dA is area of element and ω is its angular velocity.

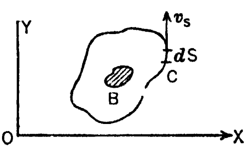

Fig. 3

(f) **Equation of Continuity:**

$$\frac{\partial u}{\partial x} + \frac{\partial y}{\partial v} = 0$$

(g) **Bernoulli's Equation:**

$p + {}^1/_2\, \rho q^2 + \rho V$ = constant along a stream line.
p = fluid pressure at any point along the stream line.
q = fluid velocity at any point along the stream line.
ρ = mass density of fluid.
V = potential energy of unit mass of fluid at point along the stream line where pressure and velocity are p and q respectively.

Each term in the Bernoulli equation is a pressure. p is usually called the static pressure.

${}^1/_2\, \rho q^2$ is the dynamic or velocity pressure.

ρV is the "difference of level" pressure.

The equation is frequently written

$$\frac{p}{\rho g} + \frac{q^2}{2g} + Z = \text{constant}$$

Each term is now a "head"; $\dfrac{p}{\rho g}$ is the static pressure head, $\dfrac{q^2}{2g}$ is the velocity head, and Z is the "difference of level" head.

(h) $\mathfrak{Z} = \dfrac{\partial v}{\partial x} - \dfrac{\partial u}{\partial y} = \dfrac{\partial^2\psi}{\partial x^2} + \dfrac{\partial^2\psi}{\partial y^2}$ = twice the average angular velocity of the fluid at a point in the flow. When $\mathfrak{Z} = 0$ the flow is irrotational.

(i) If ψ_1 and ψ_2 are stream functions of irrotational flows, then $\psi = \psi_1 + \psi_2$ is also an irrotational flow. This is called the *principle of superposition of flows*. It may be stated in analogous fashion using the velocity potential.

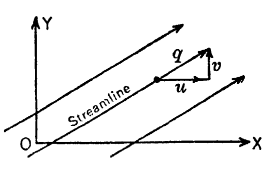

Fig. 4. Rectilinear Flow

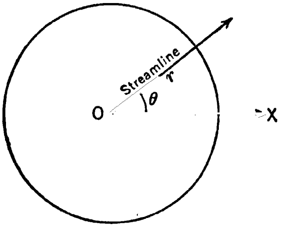

Fig. 5. Source (Sink) Flow

(j) Fundamental Flows Whose Stream Functions and Velocity Potentials Are Known:

Stream Function	*Velocity Potential*
Rectilinear Flow (Fig. 4)	
$\psi = -Vx + Uy$	$\phi = Ux + Vy$
Source and Sink Flow (Fig. 5)	
$\psi = +\frac{m}{2\pi}\theta$ (source)	$\phi = \frac{m}{2\pi}\log r$
$\psi = -\frac{m}{2\pi}\theta$ (sink)	$\phi = -\frac{m}{2\pi}\log r$

m is the volume of flow from the source *O* in unit time. It is called the strength of the source.

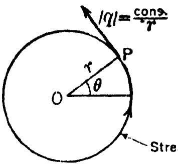

Fig. 6. Vortex or Circulating Flow

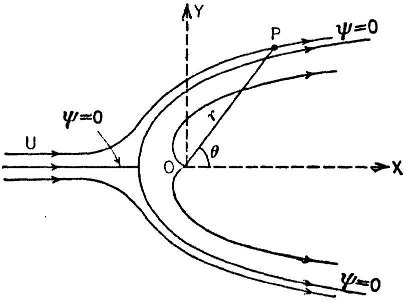

Fig. 7. Source in a Uniform Stream

Stream Function	*Velocity Potential*
Vortex or Circulating Flow (Fig. 6)	
$\psi = -\frac{\Gamma}{2\pi}\log r$	$\phi = \frac{\Gamma}{2\pi}\theta$

This flow is the only flow of an ideal fluid, whose stream lines are concentric circles, which is consistent with Bernoulli's law and the Newtonian laws of dynamics.

(k) Most Frequently Used Flows Obtained by Superposition of Fundamental Flows:

Source in a Uniform (Rectilinear) Flow (Fig. 7)

Stream Function: $\psi = +Uy + \frac{m\theta}{2\pi}$

$$\psi = +U r \sin\theta + \frac{m\theta}{2\pi}$$

The flow is separated by the $\psi = 0$ stream line as though $\psi = 0$ were a physical barrier.
m is the source strength.
U is the velocity of uniform stream (parallel to *X* axis).

Source and Sink in a Uniform Stream (Fig. 8)

Stream Function: $\psi = -Uy + \frac{m}{2\pi}\tan^{-1}\left(\frac{2ys}{x^2 + y^2 - s^2}\right)$

U is the velocity of the uniform stream (parallel to *X* axis).
m is the strength of the source and sink. Source located at *B* and sink at *A*.
$AB = 2s$

Doublet Flow (Fig. 9)

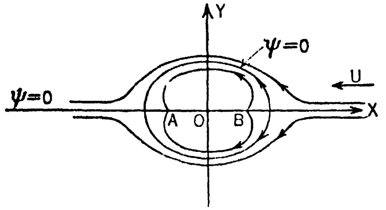

Fig. 8. Source and Sink in a Uniform Stream

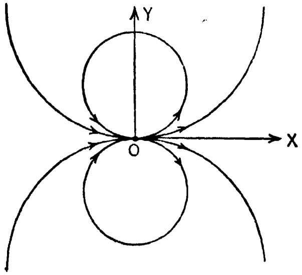

Fig. 9. Doublet

Stream Function: $\psi = \frac{ms}{\pi}\left(\frac{y}{x^2+y^2}\right) = \frac{K}{\pi}\left(\frac{y}{x^2+y^2}\right)$

A doublet is formed by letting a source and sink approach juxtaposition so that ms remains constant in value. K = strength of doublet.

Two-dimensional Flow around a Circular Cylinder (Fig. 10)

Stream Function: $\psi = -Uy + \frac{K}{\pi}\left(\frac{y}{x^2+y^2}\right)$

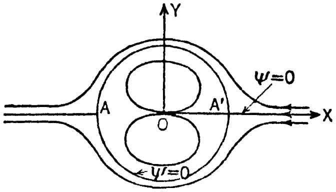

FIG. 10. Flow around a Circular Cylinder

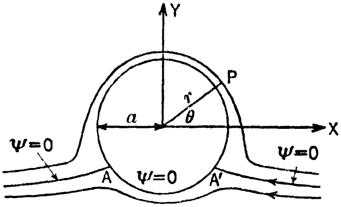

FIG. 11. Flow around a Circular Cylinder with Circulating Flow

Flow is obtained by superposing the flow due to a doublet of strength K and a uniform rectilinear flow of velocity U parallel to the X axis. $\psi = 0$ stream line consists of X axis and a circle of radius $a = \sqrt{\frac{K}{\pi U}}$ with center at the origin, O. The stream lines outside this circle determine the flow patterns of an ideal flow around a circular cylinder. A and A' are stagnation points of the flow.

Two-dimensional Flow around a Cylinder with Circulation (Fig. 11)

Stream Function: $\psi = -U\left(r - \frac{a^2}{r}\right)\sin\theta - \frac{\Gamma}{2\pi}\log r$

U is the velocity of uniform flow parallel to X axis. This is the flow velocity at points where the flow is unaffected by the presence of the cylinder.

a is the radius of the cylinder.

Γ is the strength of the circulating flow.

A and A' are stagnation points of the flow; their positions depend on the ratio $\frac{\Gamma}{aU}$

(1) Flows Obtained by Using Complex Numbers. If $Z = x + iy$, $i = \sqrt{-1}$ is a vector representing points in a plane, and ϕ and ψ are real and imaginary parts of a complex function $w = \phi + i\psi$, then this function with certain mathematical restrictions represents a possible irrotational flow of an ideal fluid. ϕ and ψ are the velocity potential and stream function respectively of this flow. The "velocity vector" $q' = \frac{dw}{dz} = u - iv$; from this the actual velocity vector q may be easily derived. By using the method of conformal transformation, shapes of various kinds and the flow patterns about such shapes may be distorted so that flows about a large number of shapes have been found.

Examples: Flow at right angles to a thin flat plate relative to the flat plate. (Fig. 12). Flow at right angles to a thin flat plate relative to the fluid (Fig. 13).

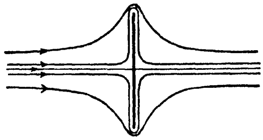

FIG. 12. Flow at Right Angles to a Thin Flat Plate Relative to the Flat Plate

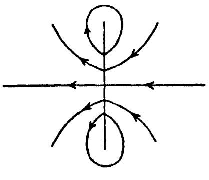

FIG. 13. Flow at Right Angles to a Thin Flat Plate Relative to the Fluid

Flow around a cylinder of arbitrary cross-section relative to the cylinder (Fig. 14).

Ideal flow around a shape used in aircraft wings relative to the wing (Fig. 15*a*). Without circulation.

Ideal flow around a wing shape relative to the wing, circulating flow added (Fig. 15*b*).

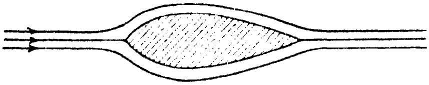

Fig. 14. Flow around a Cylinder of Arbitrary Cross Section Relative to the Cylinder

Fig. 15*a*. Ideal Flow around a Shape Used in Aircraft Wings Relative to the Wing. Without Circulation

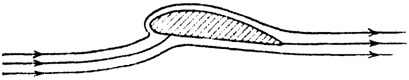

Fig. 15*b*. Ideal Flow around a Wing Shape Relative to the Wing. Circulating Flow Added

(m) General Form of Flow of an Ideal Fluid. From the forms of flows shown it may be seen that such flows have well-defined characteristics, the outstanding one being that, near the surface of a body in the fluid stream, the stream lines follow the body contours very faithfully. For complicated shapes the calculation of stream-line shapes is very difficult.

Since the theory of an ideal fluid is identical with the theory of electricity it is possible to obtain by electrical methods the shape of the lines of flow about various shapes. Hele-Shaw also used glycerin flowing between two parallel sheets of glass to show the form of two dimensional stream lines about variously shaped bodies. Any fluid motion of a viscous fluid at low velocities is like that of an ideal fluid in appearance.

15. APPLICATIONS OF RESULTS USING AN IDEAL FLUID

Bernoulli's Theorem

Flow through an Orifice in the Side of a Tank of Liquid. Assume that A and B (Fig. 16) are points on a stream line, A being in the surface of the liquid and B in the emerging jet.

$$p_A + {}^1/_2\,\rho q_A^2 = p_B + {}^1/_2\,\rho\, q_B^2 + gh\rho$$

$$p_A = p_B;\ q_A = 0$$

$$\therefore q_b = \sqrt{2gh}\ \text{(Toricelli's theorem)} \qquad (6)$$

This formula is used as the fundamental formula for flows where friction is actually present.

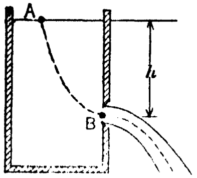

Fig. 16. Flow through an Orifice

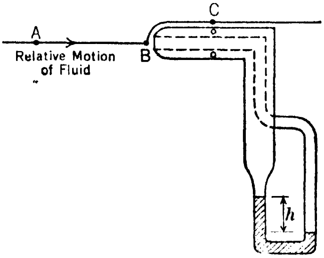

Fig. 17. Pitot-Static Tube

Pitot-Static Tube. A, B, and C (Fig. 17) are points in a stream line. Velocity and pressure at A are those obtaining in the fluid stream.

$$p_A + {}^1/_2\,\rho q_A^2 = p_B + {}^1/_2\,\rho q_B^2 = p_C + {}^1/_2\,\rho q_C^2$$

Differences in level are insignificant.

$$p_A = p_C,\ q_B = 0,\ q_A = q_C$$

$$\therefore {}^1/_2\,\rho q_C^2 = \frac{\rho}{2} q_A^2 = p_B - p_C = p_B - p_A \qquad (7)$$

$$q_C = q_A = \sqrt{\frac{2(p_B - p_A)}{\rho}} = \sqrt{\frac{2\rho' h}{\rho}}$$

where ρ' = mass density of the manometer fluid.

With proper proportions of this instrument the formula obtained furnishes very accurate estimation of fluid velocity over wide ranges of velocities and fluids.

Flow through a Venturi Tube. Take a stream line close to the wall of the tube (Fig. 18).

$$p_1 + {}^1/_2\, \rho q_1^2 = p_2 + {}^1/_2\, \rho q_2^2 = p_3 + {}^1/_2\, \rho q_2^2$$

Differences in level are insignificant.

$$p_1 - p_2 = {}^1/_2\, \rho(q_2^2 - q_1^2) = {}^1/_2 \frac{m}{\rho}\left(\frac{1}{A_2^2} - \frac{1}{A_1^2}\right) \tag{8}$$

m is the mass of flow per unit of time; A_1 and A_2 are cross-sectional areas at (1) and (2). This formula is very reliable in actual flows for proper design.

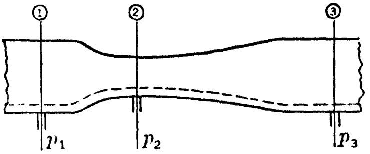

FIG. 18. Flow through a Venturi

Lift of an Airfoil. An airfoil is a body whose shape is such as to make it suitable for use in aircraft. According to Lanchester, lift of airfoils arises from the superposition of a circulating flow and the ideal flow around the airfoil. Although this circulating flow has its origin in the viscosity of the fluid, results obtained by using the ideal-flow formulas are very useful.

On stream line *AB* (Fig. 19),

$$p_A + {}^1/_2\, \rho q_A^2 = p_B + {}^1/_2\, \rho(q_B + q_{B_C})^2$$

where q_{B_C} = velocity of circulating flow at *B*.

Then
$$p_B = p_A + {}^1/_2\, \rho\, [q_A^2 - (q_B + q_{B_C})^2] \tag{9}$$

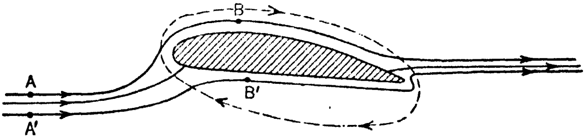

FIG. 19. Circulation and Lift

This pressure is less than the pressure at *B* when $q_{B_C} = 0$, i.e., when there is no circulation. Over the upper surface there is then a diminution in pressure with circulation present.

Similarly along $A'B'$, $p_{B'} = p_{A'} + {}^1/_2\, \rho\, [q_A'^2 - (q_B' - q_{B'_C}')^2]$ (10)

This pressure is greater than the pressure at *B'* when $q_{B'_C}' = 0$. Over the lower surface there is then an increase in pressure with circulation present. With such a diminution in pressure above the airfoil and increase in pressure below the airfoil there must be a lift.

When the actual calculation of pressure variation over the surface is made, using the potential functions of the flow and Bernoulli's theorem, the *Kutta-Joukowski theorem* of lift is obtained.

$$L = \rho V \Gamma \tag{11}$$

which is the lift per unit of span of the airfoil.

ρ = mass density of fluid.
V = velocity of flow.
Γ = strength of circulation of circulating flow.

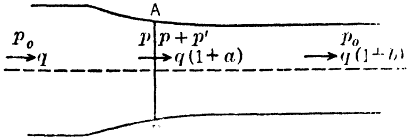

FIG. 20. Flow through a Propeller

Velocity Increase Due to an Airplane Propeller. If *AB* is the plane of the propeller disk (Fig. 20), then for flow in front of the disk,

$$p_o + {}^1/_2\, \rho q^2 = p + {}^1/_2\, \rho q^2(1 + a)^2 \tag{12a}$$

Behind the disk

$$p + p' + {}^1/_2\, \rho q^2(1 + a)^2 = p_o + {}^1/_2\, \rho q^2(1 + b)^2 \tag{12b}$$

This leads to $a = \frac{b}{2}\cdot$ This shows that the gain in speed is due partly to the increase in speed ahead of the propeller and partly to the increase behind the propeller.

Applications of Ideal-fluid Theory in Aerodynamics

This part of modern fluid mechanics is replete with applications of ideal-fluid theory. The chief reason for this will appear later. It is due partly to the fact that shapes are carefully selected, that air has comparatively small viscosity, and that compressibility has no appreciable effect until very high speeds occur.

Lift and Moment of Airfoils in Two-dimensional Flow. Dimensional analysis shows that the lift and moment of an airfoil are given in the forms:

$$L = C_L \rho \frac{SV^2}{2} \tag{13a}$$

$$M = C_M \rho \frac{SV^2}{2} \tag{13b}$$

where L = lift, ρ = mass density of air, V = velocity of air relative to the airfoil, S = plan area of airfoil, C_L = a dimensionless lift coefficient, M = moment of forces on airfoil, c = chord of airfoil, and C_M = a dimensionless moment coefficient.

Chord span = S.

Results Obtained from Ideal-fluid Theory:

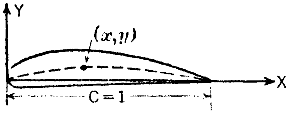

FIG. 21. Airfoil Shape

$$C_L = 2\pi(\alpha + \alpha_{L0}) \tag{14a}$$

where α = angular inclination of airfoil to relative wind. This angle is called the angle of attack; α_{L0} = angle of attack for zero lift.

$C_M = C_{M0} - {}^1/_4\, C_L$; C_{M0} = moment coefficient at zero lift.

If (x, y) is a point (Fig. 21) on the mean line of an airfoil, i.e., half way between upper and lower surface,

$$\alpha_{L0} = \int_0^1 \frac{y\,dx}{\pi x\,(1-x)^{3/2}}\,;\quad C_{M0} = \int_0^1 \frac{y\,(1-2x)\,dx}{x^{1/2}\,(1-x)^{1/2}} \tag{14b}$$

C_{M0} is referred to the origin O. Results hold for thin to medium thick airfoils. Actually the slope of C_L vs. α is constant but is usually less than 2π. The angle of zero lift α_{L0} may be quite accurately calculated from a knowledge of the geometric shape of the airfoil. C_{M0} is in general not so accurate when computed as shown although the type of variation indicated above is usually observed in experimental work.

If the mean line of an airfoil of chord c has a form given by

$$\frac{y}{c} = h\,\frac{x}{c}\left(1 - \frac{x}{c}\right)\left(1 - \lambda\,\frac{x}{c}\right) \tag{15}$$

then

$$\alpha_{L0} = \frac{h}{4}\,(4 - 3\lambda);\quad C_{M0} = \frac{\pi h}{64}\,(7\lambda - 8) \tag{16}$$

h is a thickness parameter. This result called attention to the possibility of designing airfoils with very small center of pressure travel.

Airfoils in Three-dimensional Flow. The flow around an airfoil of finite span is best described by using vortices or vortex lines. A vortex line is a line whose direction at any point coincides with the rotation vector at that point. The motion, in planes at right angles to the vortex line, is along concentric circles around it. The theory of vortex lines is due principally to Helmholtz.

Physically vortex lines or vortices have their origin in the viscosity of the fluid. Once this origin has been accounted for, the development proceeds according to the ideal-fluid theory. The principal properties of vortices used in aerodynamics are:

(i) A vortex begins or ends on the surface or on the boundaries of the fluid.

(ii) The circulation around a circuit enclosing the vortex is constant at all points of the vortex.

(iii) Vortex lines as used in aerodynamics are usually straight lines. The velocity induced by a vortex line of this character is calculated from

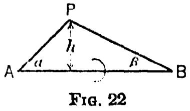

FIG. 22

$$q_P = \frac{\Gamma}{4\pi h}\,(\cos\alpha + \cos\beta)\ \text{(Fig. 22)} \tag{17}$$

Γ is the circulation around a circuit, it is called the strength of the vortex. q_P is at right angles to the plane PAB and in a sense depending on the direction of rotation around the core of the vortex.

The vortex system which describes most accurately three-dimensional characteristics of airfoils is shown by Fig. 23.

The airfoil or wing is replaced by a vortex segment AB, called the lifting line, which produces the necessary lift when combined with the flow due to the translation of the airfoil.

Trailing aft is a continuous sheet of vortices in the plane of the relative wind. This sheet has its origin in the pressure distribution around the airfoil and the influence of the pressure distribution on the flow. This plane sheet of vortices is actually unstable and rolls up into two twisted ribbon-like strands trailing aft approximately from points A and B. Principal effects are quite correctly represented by the continuous sheet, however, and the mathematics is much simpler.

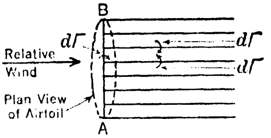

FIG. 23. Vortex System of Airfoil

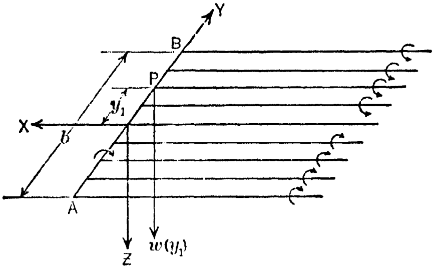

FIG. 24. Induced Velocity of an Airfoil

The principal effect of the vortex system is to add a downward velocity at all points of the span AB. This downward velocity called the *induced velocity* modifies the flow as compared with the flow around an airfoil of similar cross section but of infinite span. This induced velocity is calculated from

$$w(y_1) = \frac{1}{4\pi}\int_{-b/2}^{b/2} \frac{\frac{d\Gamma}{dy}\,dy}{y_1 - y} \qquad (18)$$

where $w(y_1)$ is the induced velocity at a point $P(0, y_1, 0)$ on the lifting line AB; b is the span of the airfoil (Fig. 24).

The addition of this induced velocity modifies the flow as shown (Fig. 25).

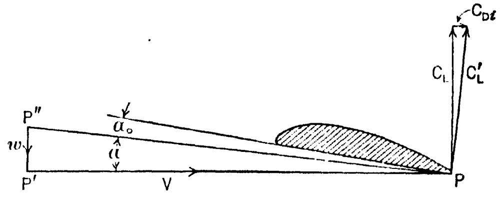

FIG. 25. Induced Drag of an Airfoil

As air approaches the airfoil of finite span the downward effect of the vortex system bends this air flow downwards so that at the wing the direction is $P''P$ as compared with $P'P$ in a two-dimensional flow around an airfoil of the same cross-section. The lift vector, varying as C_L, is tilted backwards by the angle $\frac{\omega}{V}$ radians (ω is generally small) to a new position C'_L. Since lift is measured at right angles to the relative wind V, the effect of the vortex system is represented as a component C_{Di} in what is generally considered the drag direction of the airfoil, i.e., parallel to V. The effective angle of attack is then changed from α (two-dimensional flow) to α_0 (three-dimensional flow), and $\alpha_0 = \alpha - \frac{\omega}{V}$ (radians). Also $C_{Di} = \frac{\omega}{V} C_L$. C_{Di} is called the induced drag coefficient and is given by $C_{Di} = \frac{Di}{\frac{\rho}{2}AV^2}$, where Di is the induced drag.

ρ and V are the same as before, and A the area of the wing.

C_{Di} and α_0 have been calculated by Glauert in the form

$$C_{Di} = \frac{C_L{}^2 A}{\pi b^2}(1 + \delta) \qquad \textbf{(19)}$$

$$\alpha_0 = \frac{C_L A}{\pi b^2}(1 + \tau) \qquad \textbf{(20)}$$

δ and τ depend on the variation of the circulation Γ, i.e., on the variation of load along the span. If the span loading varies as the semi-ordinates of an ellipse along the span, with the greatest ordinate at the center, δ and τ are zero. This corresponds to the ideal airfoil plan shape to produce minimum induced drag. The parameters δ and τ may be calculated for various types of airfoils.

These formulas lead to:

$$C_{D2} = C_{D1} + \frac{C_L^2}{\pi}\left(\frac{A_2}{b_2^2}(1 + \delta_2) - \frac{A_1}{b_1^2}(1 + \delta_1)\right) \tag{21}$$

$$\alpha_2^\circ = \alpha_1^\circ + \frac{57.3}{\pi}\left(\frac{A_2}{b_2^2}(1 + \tau_2) - \frac{A_1}{b_1^2}(1 + \tau_1)\right)^0 \tag{22}$$

These formulas are used to convert data obtained from airfoils of a given cross-section, given plan form, and given ratio of span to average chord to obtain data for airfoils of the same cross-section but of different plan form and ratio of span to average chord.

Combinations of Airfoils. Biplanes. The induced drag coefficient of a biplane

$$C_{Di} = \frac{C_L^2 A}{\pi (kb_1)^2} \tag{23}$$

C_L = lift coefficient of biplane.
A = total wing area of biplane.
b_1 = larger wing span of biplane.
$k = \sqrt{\dfrac{\mu^2(1 + \eta)^2}{\mu^2 + 2\sigma\mu\eta + \eta^2}}$ = Munk's span factor.
$\mu = \dfrac{b_2}{b_1}$ = ratio of spans of wings of biplane.
$\eta = \dfrac{L_2}{L_1}$ = ratio of lifts of wings of biplane.
σ = an interference factor $= f\left(\dfrac{b_1}{b_2}, \dfrac{2G}{b_1 + b_2}\right)$,
where G = gap between wings of biplane.

Table I. Values of σ

$\frac{b_1}{b_2}$	$2G/(b_1 + b_2)$						
	0	0.05	0.10	0.15	0.20	0.30	0.40
1.0	1.00	0.780	0.655	0.561	0.485	0.370	0.290
0.8	0.80	0.690	0.600	0.523	0.459	0.355	0.282
0.6	0.60	0.540	0.485	0.437	0.394	0.315	0.255

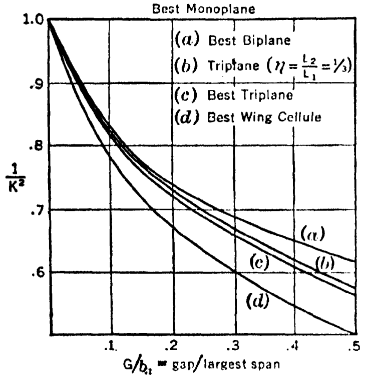

FIG. 26. Reciprocal of Munk Span Factor for Various Wing Arrangements

The induced drag or resistance is

$$D_i = \frac{2\,L^2}{\pi\rho A V^2 (kb_1)^2} \tag{24}$$

$$L = L_1 + L_2 = \text{total lift}$$

The minimum drag of a biplane is

$$D_{i\,\min} = \frac{2L^2}{\pi\rho A V^2}\left(\frac{1 - \sigma^2}{1 - 2\sigma\mu + \mu^2}\right)$$

for a given μ and σ (25)

A biplane with equal wings ($\mu = 1$) has the least induced drag of any biplane when $\eta = \dfrac{L_2}{L_1} = 1$ and

$$D_{i\,\min} = \frac{2\,L^2}{\pi\rho A V^2}\left(\frac{1 + \sigma}{2}\right) \tag{26}$$

The induced drag of multiplanes may also be calculated. The curve shown exhibits the principal properties of the induced drag of a triplane as compared with a monoplane and biplane (Fig. 26).

To be observed is that the induced drag is chiefly important at higher angles of attack.

16. DYNAMICS OF VISCOUS INCOMPRESSIBLE FLUIDS—GENERAL DISCUSSION

This phase of the subject includes the most important parts of hydraulics and aerodynamics as well as other important phases of modern engineering.

Flow of Viscous Incompressible Fluids

It is not possible to calculate the flow lines for viscous fluids in general. When the motion is slow and the viscous effects predominate, the motion is practically identical with that of ideal fluids. For many fluids, particularly for air and gases, this resemblance is true only for exceedingly slow velocities.

It will be shown later that the effect of compressibility in flows of gases is not very large until speeds comparable with the speed of sound in the gas are reached. The study of flows of viscous, incompressible fluids covers a wide range of practical cases.

The flow appearance is materially altered when viscosity is taken into account.

The flow around a sphere shown in Fig. 27 is quite representative of such flows. This does not show detailed characteristics close to the surface. Generally speaking, the flow is of the character shown. The flow in front of the sphere except in a very narrow layer close to the surface is very similar to the flow of an ideal fluid. Along a circle on the sphere surface approximately 90° from the stagnation point, the flow breaks away from the surface. On the downstream side there is a turbulent wake which is approximately a cylinder of the same diameter as the sphere. The diameter of this cylindrical turbulent wake and the conditions in the wake vary with the Reynolds' number,

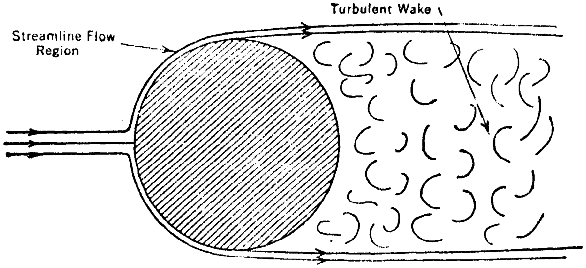

FIG. 27. Flow of a Viscous Incompressible Fluid around a Sphere

$$\frac{\rho V D}{\mu} \tag{27}$$

where ρ = mass density of fluid, μ = coefficient of viscosity of the fluid, V = flow velocity, D = sphere diameter.

As body shapes approximate more nearly to such shapes which experience has shown to give very little resistance, the turbulent wake becomes very narrow and the flow is much more like an ideal flow.

Prandtl Boundary Layer Theory

According to this theory the viscous effects in a flow along a body occur principally in a very thin layer adjacent to the surface of the body. Particles of fluid adjacent to the surface of the body adhere to the surface and have no motion relative to the surface. In the immediate neighborhood of the surface the rate of change of velocity $\frac{du}{dn}$ (n being perpendicular to the surface at the point) is comparatively large, and the viscous shear forces given by $S_T = \mu \frac{du}{dn}$ may be large even if μ is comparatively small. Outside of the thin layer the rate of change of velocity is small and the viscous shear forces are insignificant. Here then the fluid flows as an ideal fluid.

The thickness of the boundary layer is in general dependent upon $\sqrt{\frac{\mu}{\rho VL}}$, where L is a length measured along the surface.

Breakaway of Flow

If the fluid is ideal the flow follows the contours of the body closely (Fig. 28); S is a stagnation point of the flow of the ideal fluid and SS' is a stream line of the flow. If the fluid is viscous, then the flow is like an ideal fluid outside the boundary layer. There is then a stream line CD outside the boundary layer which may be regarded as a boundary of the flow since there is no flow across a stream line. As fluid approaches A, this channel between the boundary CD and the surface of the body becomes wider, the velocity decreases and the pressure increases according to Bernoulli's theorem. If there are no viscous forces the pressure increase due to divergence of this channel is sufficient to bring the fluid to rest at S. If now there are viscous forces which retard the fluid particles still more, the particles will come to rest at A. Then flow from S to A near the surface will take place, and the particles at rest with reference to the body will flow off downstream along AB. They are not in general in a stable configuration, and thus vortices appear in the wake. The same is true at point A', and hence the flow breaks away from the rear of the body and forms a turbulent wake.

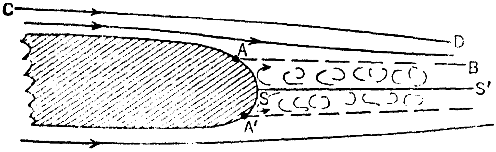

FIG. 28. Flow at the Rear of a Body

This turbulence in the wake gives rise to drag in addition to the viscous shear forces in the boundary layer. If pressure in the divergent part of the flow is reduced by suction there is less turbulence and consequently less drag or resistance.

17. FLOW OF VISCOUS INCOMPRESSIBLE FLUIDS IN SMOOTH PIPES OR TUBES OF CONSTANT CIRCULAR CROSS-SECTION

Dimensional Analysis of Pressure Drop Due to Viscosity. If the pipe is smooth, the pressure drop $\frac{\Delta p_1}{L}$ per unit length of pipe will depend on: D, the pipe diameter; $\bar{u}$, the average axial velocity of flow; ρ, the mass density of the fluid; and μ, the viscosity of the fluid.

Using the method of dimensional analysis

$$\frac{\Delta p_1}{L} = \frac{\rho \bar{u}^2}{2D} f\left(\frac{\rho \bar{u} D}{\mu}\right) \tag{28}$$

The absolute pressure drop coefficient

$$C_{\Delta p_1} = \frac{\Delta p_1 / L}{\rho \bar{u}^2 / 2D} = f\left(\frac{\rho \bar{u} D}{\mu}\right) \tag{29}$$

Theory therefore indicates that the dimensionless coefficient $C_{\Delta p_1}$ is a function of the number $\frac{\rho u D}{\mu}$. Experiments have verified that this is true. The form of the function f depends on the type of flow and is generally found by experiment.

The criterion for dynamical similarity of flows in two pipes is that $\frac{\rho_1 \bar{u}_1 D_1}{\mu_1} = \frac{\rho_2 \bar{u}_2 D_2}{\mu_2}$. When this is true the corresponding values of $C_{\Delta p_1}$ are alike. Not only may the velocities and pipe diameters be different but also the fluids may differ, as long as the corresponding values of $\frac{\rho u D}{\mu}$ are alike then the same value of $C_{\Delta p_1}$ occurs. This has also been verified by many experiments.

Laminar Flow in Smooth Pipes—Hagen-Poiseuille Law. This flow is the simplest type of flow which occurs. The fluid moves along stream lines in the axial direction. It occurs for small values of the number $\frac{\rho \bar{u} D}{\mu}$. By equating the pressure drop to the viscous shear forces and assuming a steady flow, the Hagen-Poiseuille law,

$$\frac{\Delta p_1}{L} = \frac{\rho \bar{u}^2}{2D}\left(\frac{64\mu}{\rho \bar{u} D}\right) \tag{30}$$

is derived. Flows satisfying this law are called *laminar flows.* They are also called *stream-line* and *viscous* flows. For laminar flow,

$$C_{\Delta p_1} = \frac{64\mu}{\rho \bar{u} D} \tag{31}$$

Velocity Distribution in Laminar Flow in Smooth Tubes. When laminar flow is fully established the velocity is given by

$$\frac{uy}{um} = 1 - \left(\frac{2y}{D}\right)^2 \tag{32}$$

where uy = velocity at distance y from pipe axis and um = the maximum velocity in the pipe. This maximum velocity occurs along the pipe axis and is twice the average velocity $\bar{u}$.

This velocity distribution is not instantly established at the pipe entrance. If the entrance is rounded then according to Boussinesq the true laminar velocity distribution is found at a distance x_1 given by $\frac{x_1}{D} = 0.065 \frac{(\rho \bar{u} D)}{\mu}$, from the tube entrance.

For air at atmospheric pressure and room temperature moving at an average velocity of 1 ft per sec in a pipe of 2-in. diameter $x_1 \approx 11$ ft.

Total Pressure Drop for Laminar Flow in Smooth Tubes. Let

$$\Delta p = \text{total pressure drop}$$
$$\Delta p = \Delta p_1 + \Delta p_2$$

The additional term, Δp_2, which is added to the pressure loss, Δp_1, due to viscosity, arises from the gain in kinetic energy due to the change in velocity distribution.

Schiller's value seems to give the best agreement with experimental results:

$$\Delta p_2 = 2.24 \frac{\rho \bar{u}^2}{2} \tag{33}$$

The total pressure drop is then, for a length L,

$$\Delta p = \frac{\rho \bar{u}^2}{2} \frac{L}{D} \left(\frac{64\mu}{\rho \bar{u} D}\right) + 2.24 \frac{\rho \bar{u}^2}{2} \text{ for } \textit{laminar flow} \tag{34}$$

Reynolds' Experiments. Reynolds showed that laminar flow in a circular, smooth tube changes its character gradually to a second type of flow called *turbulent flow.* He showed theoretically and by experiment that the transition from laminar flow to turbulent flow depends upon R.N. = $\frac{\rho \bar{u} D}{\mu}$. This dimensionless number is called *Reynolds' number.*

The exact value of R.N. at which the laminar type of flow changes to the turbulent type depends on the amount of disturbance in the fluid as it enters the tube. If R.N.$_1$ designates that value of R.N. at which turbulence or eddying first appears then it has been found by Ekman with Reynolds' original apparatus that R.N.$_1 \approx 50{,}000$ may be obtained by exercising extreme caution in preventing disturbance in the fluid at the pipe entrance.

It appears that for any straight, reasonably smooth pipe whose axis is horizontal R.N.$_2 \approx 2200$ is the upper limit for a flow which maintains its laminar character and for which the laminar-flow laws hold. For R.N. ≤ 2200 initial disturbance in the fluid at the pipe entrance die out.

Attention is called to the fact that if the pipe axis is not straight the value of R.N.$_2$ changes very materially. Gibson and Gridley found that R.N.$_2 \approx 260$ for flow of air through a brass tube 32 cm in diameter coiled around a drum 36 cm in diameter.

Application of Laminar Flow Laws. Critical velocity of several fluids flowing through smooth tubes with constant circular cross-section, axis horizontal.

Table II

Water, Temp. 20° C

D (in.)	½	1	2	3	4	6
$\bar{u}_c$ (ft per sec)	0.570	0.285	0.143	0.0950	0.0714	0.0475
Cfm	0.0465	0.0930	0.187	0.279	0.372	0.558
Gal per min	0.348	0.696	1.40	2.09	2.78	4.17

Castor oil, Temp. 26° C

D (in.)	½	1	2	3	4	6
$\bar{u}_c$ (ft per sec)	358.	179.	89.6	59.8	44.8	29.8
Cfm	29.3	58.5	117.0	176.0	234.0	350.0
Gal per min	220	437.	875.	1315.	1750.	2620.

These tables show that for more viscous fluids laminar flows may easily occur in commercial practice.

If the tube diameter becomes small so that the tube may be termed a capillary tube then it is comparatively common to find laminar flow taking place. This is made use of in instruments known as absolute viscosimeters. The *Hagen-Poiseuille law* is successfully employed in such instruments to obtain the value of μ for liquids.

Example: To find the pressure loss due to viscosity in pumping 100 bbl per hour of an oil of specific gravity 0.90, Saybolt viscosity 300 at average temperature, through a pipe of 4-in. diameter. A barrel is to be taken as 42 U. S. gallons.

$$\frac{100 \text{ bbl}}{\text{hr}} = \frac{4200}{3600} \times \frac{231}{1728} \frac{\text{cu ft}}{\text{sec}} = 0.156 \text{ cu ft per sec} = \frac{\pi D^2 \bar{u}}{4}$$

$$\bar{u} = \frac{4}{\pi} \times \frac{0.156}{D^2} \text{ ft per sec} = 1.790 \text{ ft per sec.}$$

$$\nu = \mu/\rho = 2.20 \times 10^{-3} \times 3.00 \times 10^2 - \frac{1.80}{3.00} \times 10^{-2}$$

$$= 0.654 \text{ cm}^2 \text{ per sec} = 7.03 \times 10^{-4} \text{ ft}^2 \text{ per sec.}$$

(See Art. 6)

$$\frac{\bar{u} D}{\nu} = 848. \quad \therefore \text{Flow is laminar.}$$

$$\frac{\Delta p_1}{L} = 0.90 \times \frac{62.4}{32.2} \times \overline{1.788}^2 \times 3 \times \frac{32}{848} = 0.633 \text{ lb per ft}^2 \text{ per ft}$$

$$\Delta p_1 = 633/144 \text{ lb per in.}^2 \text{ per 1000 ft} = 4.39 \text{ lb per in}^2 \text{ per 1000 ft of pipe.}$$

The kinetic energy term $\frac{\rho u^2}{2}$ (2.24) = 0.0434 lb per in.^{2}

$\therefore$ The total pressure drop for a level pipe of constant cross-section would be $\Delta p = 4.43$ lb per in.^{2}

Transition from Laminar Flow to Turbulent Flow in Smooth Pipes. This change from laminar flow to turbulent flow does not take place suddenly but it is generally assumed in commercial practice that the laminar law holds up to values of R.N. ≈ 2000–2200 and that thereafter the turbulent law applies.

Turbulent Flow in Smooth Tubes of Constant Circular Cross-section. In laminar flow the interaction between adjacent fluid layers gives rise to the shearing stress, S'_T, which equals the product of rate of shear and viscosity coefficient. In turbulent flow an additional interaction occurs which, because of velocity fluctuations, is due to transfer of momentum from layer to layer of the fluid.

Velocity Distribution in Turbulent Flow of Fluids through Smooth Tubes. Just as in laminar flow, the final turbulent flow distribution is not found until a certain cross-section sufficiently far from the tube entrance is reached. It is not known what this distance is except that it seems shorter than in laminar flow and is less dependent on Reynolds' number.

Karman has recently shown theoretically that the velocity distribution is given by

$$u^* = a + b \log_{10} y^* \text{ (Ref. 1 Art. 17)} \tag{35}$$

where

$$u^* = u\left(\frac{\rho}{S_{T0}}\right)^{1/2}, \quad y^* = \left(\frac{S_{T0}}{\rho}\right)^{1/2} \frac{\rho y}{\mu} \tag{36}$$

S_{T0} = shearing stress at the tube wall.
y = distance from the tube wall.
u = axial velocity at distance y.

This law does not apply near the wall where $u^* = y^*$ corresponding to a laminar layer adjacent to the wall.

Nikuradse has recently shown that the law $u^* = y^*$ holds for $0 \leq y^* \leq 10$.

Then there is a transition (smooth) to $y^* \approx 100$ when the law $u^* = 5.5 + 5.75 \log_{10} y^*$ holds (Ref. 1 Art. 17).

This formula holds for large values of R.N. $= \frac{\rho u D}{\mu}$, whereas earlier formulas of the type $u^* = A y^{*1/B}$ and fixed values of A and B held for certain ranges of R.N. only.

The formula is not simple to apply to a given case; it is of importance, however, because it is based on sound theory. In general the velocity profile in turbulent flow is " flatter " than for laminar flow. The ratio $\frac{u \max}{u}$ is more nearly constant along a pipe diameter than for laminar flow.

Pressure Drop in Turbulent Flow in Smooth Tubes. The pressure drop coefficient

$$C_{\Delta p_1} = \frac{\Delta p_1}{L} \frac{2 D}{\rho \bar{u}^2} \tag{37}$$
